

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

**GYPSUM.**

**PAGES**

Production and Imports of Gypsum in the United States—Production in the Principal Countries—*The Gypsum Cement Plaster Industry in Kansas during 1901* (by E. Haworth, p. 375)—U. S. Gypsum Co.—Iowa—Kansas—Michigan—New York—Oklahoma .....374—376

**IRON AND STEEL.\***

General Conditions of the Iron and Steel Industries during 1901—Blast Furnace Output—Production of Steel—Tin Plate—Changes in Iron and Steel Metallurgy—Iron Market Conditions in 1901—Birmingham, Ala.; Chicago, Ill.; Cleveland, Ohio—Iron Ore Shipments from Upper Lake Ports—Shipments of Lake Superior Iron Ore by Ranges—Iron Ore Receipts and Stocks—Pittsburg, Pa.—Prices of Iron and Steel at Pittsburg—Production of Pig Iron and Steel in the World—France—Germany—Russia—Spain—Sweden—United Kingdom—Charts of the World's Production of Pig Iron and Steel, and Prices at Pittsburg—*Modern Improvements in the Manufacture of Pig Iron* (by John Birkinbine, p. 393)—Factors of Progress—Iron Ores—Fuel—Blast Furnaces, Construction and Operation.....377—400

**LEAD.\***

Production and Consumption of Lead in the United States—Review of Lead Mining in 1901—Colorado—Idaho—Iowa (by S. W. Beyer, p. 403)—Missouri—Montana—Texas—Utah—Philippine Islands—Statistics of the Production and Consumption of Lead in the Principal Countries of the World—Algeria—Australia—Chart of the World's Production and New York Prices of Lead—Canada—Chile (by W. T. Matthewson, p. 410)—Germany—Greece—Mexico—Average Monthly Prices of Lead in New York—London Market—Production of White Lead, Red Lead, Litharge and Orange Mineral in the United States—Imports—*Progress in the Manufacture of White Lead during 1901* (by Parker C. McIlhiney, p. 414)—*Recent Improvements in Lead Smelting\** (by H. O. Hofman, p. 417)—New Publications—Lead Amalgams—New Lead Mineral—Importation of Lead Ores—Lead in Arkansas—Belgium—Greece—Lead Smelting at Bunker Hill, Nev.—at Llano, Mexico—Roasting Lead Ores—Mechanical Reverberatory Furnaces—Muffle Roasting Furnaces—Cooling Ores—Blast Furnace Practice Statistics—Elevator—Stock—Graphical Calculation of Charge—Rotary Blowers *vs.* Blowing Engines—Utilization of Blast Furnace Slag—Dust Catcher—Sampling Ores—Assaying—Silver—Gold Alloys—Silver—Gold—Platinum Alloys—Arsenic—Antimony—Tin and Bismuth—Slag Analysis—Purchasing Ores—Condensation of Flue-Dust—Briquetting Flue-Dust and Fine Ores—Desilverization of Base Bullion\*—Parkes Process—Electrolytic Refining—Cupellation—Lead Poisoning.....401—437

**MAGNESITE.**

Production of Magnesite in California—Various Uses—Epsom Salts—Bricks—Production in Austria—Greece—Russia.....438—439

## MANGANESE.

PAGES

Production, Imports, Consumption and Price of Manganese Ore and Metal in the United States—Colorado—Georgia (by T. L. Watson)—Virginia—World's Production—*The Production of Manganese Ores in Foreign Countries*—Belgium—Brazil—The Queluz District—Canada—Colombia—Chile—Cuba—France—Germany—Greece—India—Italy—Japan—Java—Russia—Spain—Sweden—*The Nicopol Manganese Deposits in Southern Russia\** (by Frank Drake, p. 447)—Topography—Chemical and Physical Characteristics—Labor and Wages—Mining—Ore Dressing—Transportation ..... 440—455

## MICA.

Production of Mica—Patent Molds and Machine for Splitting Mica—California—Idaho—North Carolina—South Dakota—Canada—India—*The Mica Industry of New Hampshire* (by A. J. Haskins, p. 458) .... 456—459

## MOLYBDENUM.

Production and Prices of Molybdenum Ore and Ferromolybdenum—Methods of Determination in Alloys—Electric Furnace Reduction... 460

## MONAZITE.

Production of Monazite in the United States—North Carolina—South Carolina—Brazil—Analyses of New Granada Monazite..... 461

## NATURAL GAS.\*

(By F. H. Oliphant)—Production of Natural Gas—Present Condition and Future Prospects—Comparison of Coal and Natural Gas per Indicated H.P. per Hour—*Production of Natural Gas in the United States\** (by W. H. Hammon, p. 464)—History—Gas Wells—Drilling Wells—Pipe Lines—Pumping Machinery—Gas Measurement—by Meters—by Pitot Tubes—Computed from Pressures at Two Given Points and from Minute Pressure—Geology—Appalachian Gas Field—Gas Deposits about the Cincinnati Arch—Description—Approximate Value of Natural Gas Produced from 1892 to 1900, inclusive—Pennsylvania Gas Fields—West Virginia—Ohio—Origin—Cause of Rock Pressure—Chemistry—Analyses—Combustion—Uses ..... 462—482

## NICKEL AND COBALT.\*

United States Production, Imports and Exports of Nickel—Arizona—Idaho—Nevada—North Carolina—Oregon—Wyoming—Market—Production and Imports of Cobalt Oxide—World's Production of Nickel—Nickel Mines, Plants and Production in Austria—Canada—New Caledonia (by F. Danvers Power, p. 489)—Chile—Mexico—Norway—Russia—*Cobalt Ores of New Caledonia* (by F. Danvers Power, p. 491)—*Progress in the Metallurgy of Nickel during 1901* (by T. Ulke, p. 492)—Lake Superior Power Co.—Canadian Copper Co.—Ludwig Mond Co.—Orford Copper Co.—Shuler's Process of Treating Sudbury Ores—Browne's Electrolytic Process for Depositing Nickel—Ulke's Continuous Process for Separating Nickel and Copper—Deposition of Tough Sheet

|                                                                                                                                                                                                          |         |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| Nickel—Electrochemical Behavior of Nickel-Ammonium Sulphate—<br>Electrolytic Separation of Cobalt and Nickel—Alloys—Nickel Steel—<br>Electrolytic Manufacture of Nickel Forms Direct from Solutions..... | 483—500 |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|

#### OCHEr AND IRON OXIDE PIGMENTS.

|                                                                                                                                                                                                     |         |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| United States Production, Imports and Consumption—Classifica-<br>tion of Ocher, Umber, Sienna, Iron Oxide, Venetian Red and Indian Red<br>—Manufacture—Dry Process—Wet Process—New York Market..... | 501—502 |

The only material standard of customary length authorized by the U. S. Government is the Troughton scale, whose length at 59° 62 Fahr. conforms to the British standard. The yard in use in the United States is therefore equal to the British yard.

The only authorized material standard of customary weight is the Troy pound (5,760 grains) of the Mint. It is of brass of unknown density, and therefore not suitable for a standard of mass. It was derived from

the British standard Troy pound of 1758 by direct comparison. The British avoirdupois pound was also derived from the latter, and contains 7,000 grains troy.

The grain Troy is therefore the same as the grain avoirdupois, and the pound avoirdupois in use in the United States is equal to the British pound avoirdupois.

The British gallon = 4.54346 liters.

The British bushel = 36.3477 liters.

By the concurrent action of the principal Governments of the world an International Bureau of Weights and Measures has been established near Paris. Under the direction of the International Committee, two ingots were cast of pure platinum-iridium in the proportion of 9 parts of the former to 1 of the latter metal. From one of these a certain number of kilograms were prepared, from the other a definite number of meter bars. These standards of weight and length were intercompared, without preference, and certain ones were selected as International prototype standards. The others were distributed by lot to the different Governments and are called National prototype standards.

The metric system was legalized in the United States in 1866.

The International Standard Meter is derived from the Metre des Archives, and its length is defined by the distance between two lines at 0° Centigrade, on a platinum-iridium bar deposited at the International Bureau of Weights and Measures.

The International Standard Kilogram is a mass of platinum-iridium deposited at the same place, and its weight *in vacuo* is the same as that of the Kilogramme des Archives.

The liter is equal to a cubic decimeter of water, and it is measured by the quantity of distilled water which, at its maximum density, will counterpoise the standard kilogram in a vacuum, the volume of such a quantity of water being, as nearly as has been ascertained, equal to a cubic decimeter.

## CONTRIBUTORS.

---

It is impossible to name here all who have aided us in the collection of statistics and other information for the present volume, but we give in the following pages brief biographies of the most of those who have contributed special articles, in order that readers may appreciate the high professional standing of those who have assisted in the work.

Besides the contributors of special articles, however, the preparation of this volume has been aided by the courteous co-operation of many thousands of producers who have furnished statistics of their output, and by many persons prominent in various branches of the mineral industry who have given special information. Exceedingly valuable assistance has been furnished also by the officials of many railways in the United States and Mexico, and by the State geologists, commissioners of mines, and inspectors of mines in most of the States of the Union. The statisticians of foreign countries have been extremely courteous in their co-operation, by furnishing copies of their latest publications, often in manuscripts. Professional men and experts of the whole world have rendered exceedingly valuable assistance, as have also the officials of the United States Government at Washington and abroad, and have added greatly to the value of this work. Among the thousands who have thus aided us, and by their assistance made possible the publication of this volume, as well as its predecessors, it would be invidious to select names, and in making such an attempt we should not know where to draw the line, since the contributions of almost all have been indispensable. Consequently we have decided to limit ourselves to this general acknowledgment, relying upon the belief that each of our friends will feel amply repaid for his work in the knowledge that he has contributed to the preparation of a volume which is everywhere recognized to be of the highest value to the mineral industry of the world. This high appreciation has been generously and delicately expressed by the French "Société d'Encouragement pour l'Industrie Nationale," which, since the appearance of Vol. VI., has granted to THE MINERAL INDUSTRY and its founder, the magnificent gold medal of the society, which is voted to the work or the author of the work, which, during the six preceding years, has contributed most to the cause of the national industry.

---

ARGALL, PHILIP, was born in 1854, near Belfast, Ireland, and gained his first experience in mining at the Wicklow copper mines of that island. Since then he has been engaged in important mining and metallurgical work in Wales, England, France, New Zealand, Mexico, and elsewhere. He came to the United States early in 1887 as manager of La Plata Mining & Smelting Co., of Leadville, Colo. During the last nine years Mr. Argall has devoted his attention to the treatment of ores by the cyanide process, and has taken a leading position in this field. He designed the works of the Metallic Extraction Co., at Cyanide, Colo., in 1895, and managed them until February, 1901, when he resigned to resume the practice of consulting mining and metallurgical engineer. His success in the treatment of telluride ores on a large scale, has commanded much attention in metallurgical circles. For Volume VI. he wrote an article on "Cyaniding Telluride Ores," which is recognized as the most authoritative discussion of this subject published. To the present volume Mr. Argall contributes the paper "Zinc *versus* Electrolytic Precipitation."

BIRKINBINE, JOHN, was educated at the public schools, the Friends' High School, Philadelphia, the Hill School, Pottstown, and the Polytechnic College of Pennsylvania, and later entered the army service during parts of 1863 and 1864. Mr. Birkinbine has been actively engaged in many important hydrographic surveys and continues as consulting engineer in this specialty. Mr. Birkinbine has reported upon iron ore mines and others in most of the States, Canada and Mexico, and was a pioneer in recommending the establishment of blast furnaces on the Great Lakes. He was consulting engineer for the receivers of the Philadelphia & Reading Coal & Iron Co., and acted also as consulting engineer for Mr. Thomas A. Edison and for Messrs. Witherbee, Sherman & Co. At the present time he is the consulting engineer for the Cambria Steel Co., the Colorado Fuel & Iron Co., and other important corporations. Mr. Birkinbine is the expert on iron ore

and manganese ores for the United States Geological Survey, and in 1889 he prepared the report on iron ores for the Eleventh Census. For many years Mr. Birkinbine has been a member of the American Institute of Mining Engineers, and other prominent associations. He is president of the Franklin Institute of Philadelphia, as well as of the Pennsylvania Forestry Association. He served on the Jury of Award of the World's Columbian Exposition, of the Cotton States & International Exposition, and of the Pan American Exposition, etc. To the present volume he contributes the monograph, "Modern Improvements in the Manufacture of Pig Iron."

BREWER, WILLIAM M., was born in England, and acquired his education principally at the Philological School. He was a pioneer in the Black Hills of South Dakota, and learned practical mining and milling at the works of the Homestake Co. Mr. Brewer began practice as a consulting mining engineer and geologist in 1890, and examined and reported on the gold fields of Alabama in 1895, and reopened the old gold mine in Cherokee County, Georgia. He has made examinations in the Black Hills of South Dakota, in Arizona, Colorado, the Southern States, and British Columbia, and during 1901 traveled through British Columbia and southeastern Alaska on expert work. He is a member of a number of engineering societies, and has contributed to their proceedings and to the *Engineering and Mining Journal*. He contributes to the present volume the reviews for 1901 of gold and silver mining in Alaska and British Columbia, and copper mining in Canada.

CARPENTER, FRANKLIN R., was born in West Virginia. Educated as an engineer, with the degrees of M.A. and Ph.D., he began his mining work in the West Virginia coal and oil fields, and continued it in Colorado. In 1886, as Principal and Professor of Geology and Mining in the South Dakota School of Mines, he adapted the Kongsberg process of pyritic smelting to the South Dakota siliceous ores. For 10 years he was general manager of the Deadwood & Delaware Smelting Co. works, whose plant he designed and built. He designed also the plant for the Clear Creek Mining & Reduction Co., at Golden, Colo., of which company he is now general manager. Dr. Carpenter is a fellow of the Geological Society of America and of the American Institute of Mining Engineers. To the Institute he has contributed several papers, and other essays from his pen have treated of the geology and the mines of the Black Hills, and of pyritic smelting. To this volume Dr. Carpenter contributes the paper, "Pyritic Smelting."

DOUGLAS, JAMES, was born in Canada, but has made his home in the United States since 1875. His first experience in mining and metallurgy was acquired in trying to unravel the complicated affairs of an unsuccessful Canadian mining enterprise. He came to the States in order to take charge of copper works established in Phoenixville, Pa., for the utilization of local copper ores, whose supply, however, proved deficient; but he is best known through his connection with the copper industry of Arizona, with which he has been intimately associated almost since its initiation. He is a past president of the American Institute of Mining Engineers, and president of the Copper Queen Consolidated Mining Co., and of other Arizona concerns, including the Arizona & South-eastern Railroad Co. Such original work as he has done was chiefly in connection with the late eminent chemist, Dr. T. Sterry Hunt, in the field of the hydrometallurgy of copper. Mr. Douglas has contributed to the present volume the notes on the copper industry in Arizona.

DRAKE, FRANK, was graduated from the Michigan College of Mines in 1890, and afterward studied engineering and metallurgy at the Massachusetts Institute of Technology. He was employed at iron and copper mines in Michigan and at silver mines in Colorado until 1896, when he became superintendent of manganese mines in Russia for the Nicopol-Mariopol Mining & Metallurgical Co. While engaged with this organization he examined in its interest iron and manganese mines in various parts of Russia and the Caucasus. On returning from Russia in 1898 he became assistant manager of the War Eagle and Center Star gold-copper mines, B. C., resigning this position later to become chief engineer of the Oliver Iron Mining Co., and upon the formation of the United States Steel Corporation he became chief engineer of its iron mines. Mr. Drake contributes to this volume the paper, "The Nicopol Manganese District in Southern Russia."

**ECKEL, EDWIN C.**, was graduated from the School of Civil Engineering, New York University, in 1896, and supplemented his college work with a post-graduate course in geology under Prof. J. J. Stevenson. In 1899 he became connected with the New York State Museum, and received an appointment as Assistant in Geology in 1900. Mr. Eckel has published reports on the cements of New York State, on the quarry industry, the emery deposits of Westchester County, N. Y., and on several minor economic products. He has also reported, for the U. S. Geological Survey, on the clays of western Mississippi and Tennessee, and has published a number of papers, chiefly on cement technology. Mr. Eckel is a member of the American Society of Civil Engineers, and of the Society of Chemical Industry, and to the present volume he contributes the article on "The Slag Cement Industry in the United States during 1901."

**DVORKOVITZ, PAUL**, in 1877-78 was appointed sanitary chemist to the hospital of the Princess of Oldeburg in the Russo-Turkish war. Afterward he studied chemistry at the University of Moscow, and in 1883 he took the position of technical manager of an oil refinery at Baku. There he discovered a method of utilizing the soda and acid by-products obtained in course of refining, and invented a special still for continuous distillation. Later, in England, Mr. Dvorkovitz worked to develop the use of solar oil for enriching water gas, and he invented an apparatus for gasifying oil and producing aromatic hydrocarbons. Five years ago he built for the Mineral Oils Corporation in London the first refinery in England, and prepared all the plans for another large refinery erected by the Shell Transport & Trading Co., Ltd., in Borneo. In 1899 he started the *Petroleum Review*, and in 1900, the *Oil World*. In 1900 Mr. Dvorkovitz was instrumental in forming the petroleum congress in Paris, in August, which resulted in the establishing of a permanent commission for organizing international petroleum congresses every two years in the future, with a central committee in Paris, and local committees all over the world. Mr. Dvorkovitz contributes to this volume the paper, "Petroleum."

**FALDING, F. J.**, was born in England and was educated at Amersham Hall, London, and at the Bergakademie at Freiberg in Saxony, although he did not graduate from the latter. In 1878-79 he made a study of the Canadian apatite deposits, and in 1880 returned to Europe, where he studied the manufacture of sulphuric acid and fertilizers in England and Germany. In 1881 he returned to Canada and unwatered the Capelton pyrites mines, now worked by the Nichols Chemical Co. From 1882 to 1886 he practiced as a mining engineer, with headquarters in New York, making a specialty of pyrites and phosphate mining. In 1888 he entered the employ of the Grasselli Chemical Co. as engineer, in charge of its mines, becoming in 1890 the chief engineer. During this time he designed the company's new works at East Chicago, Ill. In 1889 he was one of the charter members and first directors of the Canadian Institute of Mining Engineers. In 1895 he established himself in New York as a consulting chemical engineer, since when he has constructed and rebuilt many sulphuric acid plants in various parts of the United States. He contributes to this volume the paper, "Progress in the Sulphuric Acid Industry in 1901."

**HECKSCHER, AUGUST**, was born at Hamburg, Germany, and educated in Germany and Switzerland. He was actively connected with the anthracite coal mining industry in the United States from 1868 to 1882, and since 1881 he has been engaged in the zinc mining and manufacturing industry in New Jersey, Pennsylvania, Illinois, Wisconsin and Missouri. At present he is general manager of the New Jersey Zinc Co. Mr. Heckscher contributes to this volume the review notes on the zinc industry of New Jersey.

**HOFMAN, H. O.** was born in 1852 at Heidelberg, Germany. He studied at the Bergakademie at Clausthal, where he graduated in 1877 in mining engineering and metallurgy. He was then appointed chemist and assistant at the smelting and refining works at Lautenthal in the Harz. In 1881 he came to the United States and was employed successively at Mine La Motte, in Missouri, at the Argentine smelting and refining works of the Consolidated Kansas City Smelting & Refining Co., and as metallurgist of the Delaware Lead Co., in Philadelphia. When the last named works were closed he went to Colorado, and after running the Rico smelter for a short time went to Park City, Utah, to study the amalgamation and lixiviation of silver ores at the Ontario mill. After a

short time spent in charge of a smeltery in Mexico he was appointed assistant to Prof. Richards at the Massachusetts Institute of Technology in Boston; from there he went to the School of Mines of South Dakota as professor of metallurgy and assaying, where he remained until called back to the Massachusetts Institute of Technology to the professorship of metallurgy, which he now holds. Dr. Hofman has made numerous contributions to technical literature, his most important work being the admirable treatise on *The Metallurgy of Lead*. For his paper on the "Dry Assay of Tin Ores" the degree of Ph.D. was conferred on him by the University of Ohio. For the present volume he has contributed the article "Progress in the Metallurgy of Lead."

HAMMON, W. H., was born in 1860. He was graduated at Allegheny College, Meadville, Pa., in 1881, and afterward spent one year in post-graduate work in Columbia University, Washington, D. C., and two years in advance physical and mathematical work at Cornell University, Ithaca, N. Y. In the early eighties he was employed on the engineering corps of the Standard Oil interests in the Bradford and adjacent fields, and was afterward connected with the United States Weather Bureau, serving as observer at Cleveland and St. Louis, and as Forecast Official in St. Louis and San Francisco. In January, 1899, he was appointed professor of meteorology in the Weather Bureau, which position he shortly afterward resigned to accept a position as assistant to the general manager of the Philadelphia Company, at Pittsburg, Pa., which position he still holds. Mr. Hammon contributes to this volume the paper "Natural Gas."

OLIPHANT, F. H., was born at Uniontown, Fayette County, Pa., August 30, 1845, and was graduated from the Polytechnic College of Pennsylvania, at Philadelphia, in 1868, receiving the degree of civil engineer. For several years after graduation Mr. Oliphant was employed by the Pennsylvania Railroad in construction work, and later in the operation of bituminous coal mines in western Pennsylvania and Kentucky. For the past fifteen years he has been employed as geologist in the petroleum and natural gas fields of the United States and foreign countries, and during the last five years of this period he has compiled the reports on petroleum and natural gas for the United States Geological Survey. To the present volume Mr. Oliphant contributes the reviews of the natural gas and petroleum industry in the United States during 1901.

HOFMANN, OTTO KAR, was born in 1843 at Rusberg, in Austria-Hungary, and educated at the Realschule and Polytechnic Institute in Vienna, and the Bergakademie at Freiberg, graduating from Freiberg in 1866. In 1867 Mr. Hofmann came to the United States, entering the assay office of Guido Kuestel in San Francisco as partner as his first venture. Mr. Hofmann has been largely identified with leaching processes for the extraction of gold and silver from ores. In 1868 he erected at La Dura, Sonora, Mexico, the first lixiviation works operated in North America, following its success with the construction of other works at La Trinidad and San Marcial, Sonora, and Trinufo, Lower California. He has served as metallurgist for various amalgamation and chlorination mills in Nevada and California, and since 1880 he has been occupied almost exclusively in hydrometallurgy, having been engaged successively at St. Louis, Mo. (1882-3); Cusihiuriachic, Chihuahua (1885); Yedras, Sinaloa (1886-7); Cusihiuriachic (1887); Parral, Chihuahua (1888); Cusihiuriachic (1890-94); Sombrerete and Parral (1894). In 1895 Mr. Hofmann took charge of the leaching department of the Consolidated Smelting & Refining Co., at Argentine, Kan., and in 1897 he displaced the Hunt & Douglas process then in use, by a process which freed, in one operation, copper sulphate solutions from iron, arsenic, antimony, and other impurities. Mr. Hofmann is now consulting chemist for the American Smelting & Refining Co., and consulting metallurgist for the Avino mines of Mexico, and chemical director of the United Zinc & Chemical Co., of Kansas. Mr. Hofmann has contributed largely to metallurgical literature, chiefly through the medium of the *Engineering and Mining Journal* and the *Transactions of the American Institute of Mining Engineers*. Supplementing his excellent article in THE MINERAL INDUSTRY, Vol. VIII., Mr. Hofmann contributes to the present volume the paper "Progress in 1900 and 1901 in the Manufacture of Blue Vitriol by Hofmann's Method."

INGALLS, WALTER RENTON, was born at Lynn, Mass., in 1865, and was graduated from the

Massachusetts Institute of Technology, in 1886. In 1886-90 he was engaged in mining at Leadville and elsewhere in Colorado. In 1890-92 he was assistant editor of the *Engineering and Mining Journal*, resigning that position to go to Mexico to open tin mines in the State of Durango for the Pittsburg & Mexican Tin Mining Co. In 1893 and 1894 he established himself in New York, and visited professionally various mining districts in the United States, Canada, Belgium, Germany and Poland, devoting himself especially to the metallurgy of zinc. During a part of 1894 he had charge of the operations of the Illinois Phosphate Co., in Florida, and later in the year became connected with the Gold & Silver Extraction Co. of America, Ltd., as metallurgist. In 1895 he was manager of a cyanide works at Cripple Creek, Colo., and in 1896 of copper-matte smelting works in Durango, Mexico, returning to New York in 1897. He was assistant editor of *THE MINERAL INDUSTRY*, Vols. V., VI. and VII., and is now located in Boston, Mass., as consulting engineer. For this volume he contributes the paper, "The Progress in the Metallurgy of Zinc in the United States during 1901."

KERSHAW, JOHN B. C., was born at Southport, Eng., and was educated at Bickerton House School, Southport, and at Owens College, Manchester. In 1879 Mr. Kershaw entered the Sutton Lodge Chemical Works, St. Helens, Eng., and remained there for twelve years, rising in this period to the position of chief chemist and assistant manager. In 1892 Mr. Kershaw went to Germany and pursued his studies of chemistry and allied sciences at Bonn University. Since 1896 he has been engaged in practice as consulting chemist and as a technical journalist in London, and has devoted himself especially to work relating to electro-chemical processes and industries. He is a member of several chemical and other societies, and is also on the staff of abstractors for *The Journal of the Society of Chemical Industry* and for *Science Abstracts*. Mr. Kershaw has written numerous articles in recent years upon electro-chemical and electro-metallurgical subjects, and is the translator and editor of Dr. Neumann's German work on *Electrolytic Methods of Analysis*. To the present volume he contributes the articles, "Progress in the Aluminum Industry in 1901," "Chlorates and Hypochlorites in 1901," and the general review of the "Progress in the Electro-Chemical and Electro-Metallurgical Industries in 1901."

LENHER, VICTOR, was graduated in chemistry in 1893 from the University of Pennsylvania, and for three years following he was assistant to Prof. W. B. Rising in the chemical department of the University of California. From 1896 to 1898 he was engaged in pursuing special studies in chemistry, mineralogy and geology at the University of Pennsylvania, receiving the degree of Ph.D. from that institution in 1898. Dr. Lenher has been a regular contributor to various chemical journals. He was on the staff of instruction in chemistry at Columbia University from 1898 to 1900, and is at present assistant professor of general and theoretical chemistry at the University of Wisconsin. He contributes to this volume the article, "Rare Elements."

LEWIS, FREDERICK H., studied civil engineering at the University of Pennsylvania, graduating in 1878. He then became heliotroper on the United States Coast Survey, serving during the summer of 1878, and for three years afterwards was assistant engineer of the construction department of the Pennsylvania Railroad Co.'s lines west of Pittsburg. From 1882 to 1885 he was superintendent of bridges and buildings of the Northern Pacific Railway, being situated at St. Paul, Minn., and he was also in charge of the location of the company's terminal lines between St. Paul and Minneapolis. In 1885 and 1886 he was resident engineer of the South Pennsylvania Railroad, at Sideling Hill tunnel, Fulton County, Pa. From 1886 to 1893 he was an Eastern manager of the Pittsburg Testing Laboratory at Philadelphia. Since 1893 he has been practicing as consulting engineer at Philadelphia, and has also been consulting engineer for the firm of Booth, Garrett & Blair, in their department of physical tests and inspection. He is manager and chief engineer of the Virginia Portland Cement Co., and contributes to this volume the paper on "The Cement Industry in the United States during 1901."

McILHINEY, PARKER C., was born in 1870, at Jersey City, N. J., and in 1892 he was graduated from the School of Mines, Columbia College, in the course of chemistry, receiving in 1894 the degree of Ph.D. for special work in chemistry and physics. From 1894

until 1900 he was connected with the Departments of Chemistry and Metallurgy, Columbia University, and, in addition to general chemical practice he has given considerable time to the manufacture of glass, metal, enamel and pottery art works. Dr. McIlhiney contributes to this volume the paper, "The Manufacture of White Lead."

MATHER, HENRY A., was born March 31, 1870, and attended Rutgers College, Scientific School, for two years, completing his education with a special course in chemistry at Johns Hopkins University, graduating in 1891. From 1893 to 1899 he was at first vice-president, later president, of the Greenpoint Chemical Works of Brooklyn, N. Y., which works was the pioneer in the United States in recovering cyanides from "gas mass" and spent purifying material. Mr. Mather devised several processes which were used in connection with the manufacture of iron oxide for gas purification and recovery of by-products from spent oxide. From 1899 to 1901 he was secretary, and during part of 1900 metallurgist in charge of the initial smelting operations of the Verde Queen Copper Co., at Jerome, Ariz. Mather has made contributions on technical subjects to the *American Gas Light Journal* and the *Engineering and Mining Journal*, and since April, 1902, has been assistant on the editorial staff of the present volume.

MATHEWS, JOHN ALEXANDER, was born in Washington, Pa., May 20, 1872, and was graduated from Washington and Jefferson College in 1893 with the degree of B.Sc. Later he entered Columbia University as a graduate student in chemistry, and received therefrom the degrees of M.A. and Ph.D. He was awarded by Columbia University, the University Fellowship in Chemistry in 1897, and the Barnard Fellowship for the Encouragement of Scientific Research in 1900, 1901 and 1902, and by the Iron and Steel Institute of Great Britain, the Andrew Carnegie Research Scholarship in 1901. From 1897 to 1900 Dr. Mathews was instructor in the Department of Chemistry of Columbia University. He resigned in 1900 to follow research work on alloys in the laboratory of Prof. Sir William C. Roberts-Austen, London, which has since been continued at Columbia University under Prof. Henry M. Howe. President McKinley appointed Dr. Mathews a member of the United States Assay Commission in 1900, and the first Andrew Carnegie gold medal for research was awarded him by the Iron and Steel Institute in 1902. Dr. Mathews is a member of the American Chemical Society, being the secretary and treasurer of the New York section. He has written many scientific articles, and for the present volume he has contributed the paper "Alloys as Solutions."

MEMMINGER, C. GUSTAVUS, was born at Charleston, S. C., in 1864, and began work as mining engineer in the phosphate industry of South Carolina. He took an active part in the mineral development of the South, and when the Florida phosphate deposits were opened he was prominent in the furthering of the new industry there. After building and successfully operating the largest pebble phosphate mining plant in Florida, Mr. Memminger, in 1900, moved to Nashville, Tenn., from whence he removed to Florida in 1901, and is at present actively engaged in the development and mining of phosphates. Mr. Memminger contributes to this volume the paper, "Progress in the Phosphate Mining Industry in the United States during 1901."

MILLER, EDMUND H., was graduated from the chemical course of Columbia School of Mines in 1891, and received the degree of Doctor of Philosophy from Columbia University in 1894. At present, Dr. Miller is Adjunct Professor of Analytical Chemistry and Assaying at Columbia University, and is giving special attention to inorganic chemistry and assaying. Prof. Miller is the author of "Calculations of Analytical Chemistry and Notes on Assaying" (with Dr. P. de P. Ricketts), and has written numerous articles in the chemical journals on the results of his original work in chemistry. To the present volume Dr. Miller contributes "Reviews of Analytical Chemistry Relating to Barium, Boron, Bismuth, Chromium, Gold, Manganese, Potassium, Silver, Sulphur and Tin."

NEWLAND, DAVID H., was graduated from Hamilton College in 1894, and for three years thereafter was a student of geology and related sciences at the Universities of Munich, Heidelberg and Columbia. In 1897 and 1898 he was employed by the State of New York mapping the geology of portions of the Adirondack Mountains; the results

**CONCLUSIONS**

of this work appearing recently in the Eighteenth Annual Report of the State Geologist. He has been engaged from time to time in other geological investigations, particularly in determining the petrographical relations of metamorphosed rocks, and has contributed to scientific journals. For the past two years, until April, 1902, Mr. Newland has been connected with THE MINERAL INDUSTRY as assistant on the editorial staff.

OBALSKI, J., was born in France in 1852, and studied at the Ecole des Mines at Paris; after graduation he occupied several positions in connection with the mining industry in France and Spain, and visited various mining districts in those countries and Belgium and Portugal. In 1881 he was called by the government of the Province of Quebec to fill the position of mining engineer and inspector of mines, which post he still occupies. He has contributed to the present volume notes on asbestos, chrome ore, copper ore and mica mining in Quebec.

POWER, FREDERICK DANVERS, was born at Lee, England, in 1861. He received his technical training in Swansea, South Wales; at the Royal School of Mines, London, and at the Bergakademie of Clausthal, Germany. He has travelled in South America and North Africa, but has spent most of his professional life in various parts of Australasia and the South Seas, having arrived in Victoria in 1885. He has held various appointments for British and Colonial companies, and has contributed several scientific papers to English and Colonial journals and transactions of scientific societies. He is also the author of a "Pocketbook for Miners and Metallurgists," published by Messrs. Crosby, Lockwood & Son. He has been on the council of the Australasian Institute of Mining Engineers from its foundation, and has acted both as vice president and president; he was formerly examiner of Mining at the University of Melbourne; vice-president of the New South Wales Chamber of Mines, and is a life member of the American Institute of Mining Engineers, the Institute of Mining and Metallurgy and the Royal Geological Society, London. For the present volume he contributes articles on "Phosphates of Ocean and Pleasant Islands (Gilbert and Marshall Groups)," and "Notes on the Nickel, Chrome and Cobalt Deposits in New Caledonia."

PRATT, JOSEPH HYDE, was born at Hartford, Conn., on February 3, 1870, and was graduated from Sheffield Scientific School, Yale University, with the degree of Ph.B., in 1893, and Ph.D. in 1896. Mr. Pratt was instructor in mineralogy at Yale from 1895 to 1897. Since then he has acted as State Mineralogist of North Carolina, and field assistant of the United States Geological Survey since 1898, besides acting as lecturer on mineralogy for the University of North Carolina. He has contributed a number of articles on mineralogy, geology and chemistry to scientific magazines, and is a member of several geological, geographical and engineering societies. Dr. Pratt contributes to the present volume the review of gold mining in North and South Carolina, and the paper "Progress in the Corundum and Emery Industries during 1901."

RICHARD, ROBERT HALLOWELL, professor of mining and metallurgy at the Massachusetts Institute of Technology, was born in 1844 at Gardiner, Me. He graduated in 1868 from the Massachusetts Institute, being a member of its first class, and became assistant in chemistry in the corps of instruction, passing successively to the post of instructor, assistant professor of chemistry, professor of mineralogy and assaying, professor of mining engineering, and in 1884 to his present professorship of mining and metallurgy. Under his administration the mining and metallurgical laboratory, which was the first of its kind in an educational institution, has been developed to a high degree of excellence, and has been a model for similar laboratories in other colleges. In addition to his professional duties, Prof. Richards has been actively engaged as a consulting engineer in mining and metallurgical work, and has been the inventor of several ingenious devices, which have found extended use in practice. He has contributed many valuable papers to the technical press, and to the transactions of various scientific societies. His most recent work on the principles of ore dressing is the admiration of the entire body of engineers engaged in that branch of metallurgy. To this, as in previous volumes, he has contributed the reviews "Progress in Ore Dressing" and "Progress in Gold Milling."

RIES, HEINRICH, Ph.B., A.M., Ph.D., was graduated in 1892 from Columbia College,

School of Mines, New York City. After his graduation he was employed as assistant geologist on the New York State Geological Survey, and during the World's Fair at Chicago he was assistant director of the New York scientific exhibit. He has prepared much valuable data on the clays of New York State, and in a special trip made to Europe to investigate the foreign clay-working industry, he studied at the University of Berlin the German methods for the laboratory investigation of clays. In 1895 he was judge of clays at the Cotton States Exhibition, and member of the jury of awards at the Pan-American Exposition in 1901. Dr. Ries has written a number of papers on economic geology, and has prepared special State reports on the clays of New York, Michigan, Alabama, North Carolina, Louisiana, Maryland and New Jersey. From 1898 to 1902 he has been instructor in economic geology in Cornell University, Ithaca, N. Y., receiving in the latter year the position of assistant professor. Dr. Ries is an associate editor of the *Geologische Centralblatt*. To this volume he contributes the paper, "Fire Clays and Their Manufacture into Refractory Materials" and "Review of Literature of Clays and Clay Products."

ROSSI, AUGUSTE J., was born in Paris in 1839. In 1855 he was graduated from the University of France, and he received his degree of civil and mining engineer from the Ecole Centrale in 1859. Soon afterward he came to the United States, of which he has long been an adopted citizen. Mr. Rossi, in the course of his professional practice, has been with the Morris & Essex Railroad, with the Boonton blast furnaces and with the New York Ice Machine Co. For the past eight years he has devoted himself particularly to electro-metallurgy, and as consulting mining engineer has been engaged in the study of the metallurgy of titanium. He is a member of the American Institute of Mining Engineers and of the American Chemical Society, and various articles from his pen have appeared in the published proceedings of these societies, and in other technical publications. To this volume Mr. Rossi contributes the paper, "The Manufacture of Liquefied Carbonic Acid Gas."

SANDERS, WILBUR E., was graduated from Columbia College School of Mines, as mining engineer in 1885, and following graduation spent several years working in every manual capacity in various mines, mills and metallurgical establishments of the West, to gain practical experience. As examining engineer Mr. Sanders has travelled over and examined a large part of the metalliferous region of the West, and has both superintended and operated properties in Idaho, South Dakota, Washington, British Columbia, Colorado and Montana; in the latter State he was in charge of the exploiting of the noted East Pacific mines. His latest connection, that of geologist to the Amalgamated Copper Co., of Butte, Mont., he resigned, recently, to devote himself to his forthcoming work on "Mine Timbering and the Support of Earthworks." His contribution to the present volume of the mineral industry is a preliminary paper on this subject.

SAUVEUR, ALBERT, studied four years at the Ecole des Mines at Liège, Belgium, and then at the Massachusetts Institute of Technology, where he was graduated in 1889. After one year in the chemical laboratory of the Pennsylvania Steel Co., at Steelton, Pa., he became connected with the South Chicago works of the Illinois Steel Co., with which he remained six years, most of the time in charge of the experimental laboratory. Since February, 1897, he has been proprietor and manager of the Boston Testing Laboratories at Boston, and is now assistant professor at Harvard University, and editor of *The Metallgraphist*. From 1898 to 1900 he was lecturer on metallography at the Massachusetts Institute of Technology. Mr. Sauveur is a member of several scientific societies, and has been a contributor to numerous technical publications. He has a world wide reputation as an expert in his specialty, the investigation of the micro-structure of metals, and its bearing upon their technology. Mr. Sauveur contributes to this volume the paper, "The Progress in Metallography in 1901."

SCHNIEWIND, FREDERICK, was born at Bochum, Westphalia, in 1861. He studied at the institutes of technology at Charlottenburg and Munich and at the universities of Berlin, Munich and Heidelberg, receiving the degree of Ph.D. at the latter university. He then entered the laboratory of a Westphalian blast furnace and subsequently had

charge of analytical laboratories at Cleveland, O., and Crystal Falls, Mich. Since its inception he has been connected with the United Coke and Gas Co., which builds and operates by-product coke ovens, especially of the Otto-Hoffmann type. He adapted by-product coke ovens to the manufacture of illuminating gas and has made a number of improvements in their construction. He is the author of numerous articles on coal distillation in coke-ovens, and to the present volume he contributes the paper, "Manufacture of Coke in the United States, with Special Reference to the Markets for By-Products."

SPIREK, VINCENTE, was born in 1852, at Bubovice, near Prag, Bohemia, and was graduated from the Bergakademie at Pribram in 1876. He entered at once into active mining and in 1878-1879 became an officer of the government mining bureau in Bosnia, Herzegovina. He was employed under Exeli in Idria, and from 1876 to 1890 he was associated there with Cermak in the remodeling of the works and the design of the well-known Cermak-Spirek quicksilver furnace. After service as an officer in the army in Bosnia and Herzegovina he resigned his position of Oberhuetteningenieur in the State Mines Direction to take charge of the quicksilver works at Monte Amiata, Italy. Mr. Spirek has received several government medals in recognition of his special work as an engineer, and he has written a number of technical articles. To the present volume he has contributed notes on the working results of the Cermak-Spirek furnace on quicksilver ores and the paper, "The Cermak-Spirek Furnace for Roasting Zinc Ores."

STRUTHERS, JOSEPH, was born at New York City in 1865, and attended the School of Mines, Columbia College (now Columbia University), graduating therefrom in the course of chemistry in 1885, and in 1895, receiving the degree of Ph.D. from that institution. For three years after his graduation he was assistant in the department of mineralogy at Columbia University, and from thence until 1900 he was on the staff of instructors of the department of metallurgy, first assisting Dr. Thomas Egleston, and later Prof. Henry M. Howe; later becoming honorary lecturer in metallurgy at Columbia University. In 1896 he organized and conducted the first summer school in practical metallurgy of Columbia University, which was held at Butte, Mont., and, in the following year, the summer schools at Chicago and Pittsburg were under his charge. In 1898 and 1899 he assisted at the summer schools held in Pennsylvania and Maryland. Dr. Struthers has visited many metallurgical plants in the United States and Europe, and he has carried on special investigations in calorimetry, measurement of furnace temperatures, microscopical examination of metals and slags, and work of like character. He has written numerous articles for the *Engineering and Mining Journal* and the *School of Mines Quarterly*, and from 1892 to the present time he has been on the Board of Editors of the latter publication, acting for most of this period as business manager. As assistant editor of *THE MINERAL INDUSTRY*, Vols. VIII. and IX. and Editor of Vol. X. he has had entire charge of their preparation, and has contributed to them by far the greater number of the unsigned articles. In November, 1901, Dr. Struthers was appointed Field Assistant to the United States Geological Survey, and he has contributed many articles on the minor metals and minerals for the forthcoming volume of *The Mineral Resources*.

TUCKER, SAMUEL AUCHMUTY, was graduated in 1895 from Columbia School of Mines in the course of chemistry, and became assistant in physiological chemistry, College of Physicians and Surgeons in 1895; assistant in toxicology, 1896; assistant demonstrator in chemistry and physics, 1896; and tutor in industrial chemistry at School of Applied Science, Columbia University, in 1897. Mr. Tucker is a member of several chemical societies and has contributed the results of his research work with the electric furnace at high temperatures to various chemical publications. To the present volume he contributes the paper, "Manufacture of Potassium Cyanide."

ULKE, TITUS, was born in 1866, at Washington, D. C. In 1889 he was graduated from the Royal School of Mines at Freiberg, Saxony, as metallurgical engineer. After spending some time in visiting the various mines and metallurgical works in Europe, Mr. Ulke returned to this country and was engaged as chemist to the Harney Peak Tin Co., in South Dakota. In 1891 he became assayer for the United Smelting Co., and afterwards was

engaged by the Anaconda Mining Co., as chemist at its electrolytic copper refining works. In 1893 Mr. Ulke acted as metallurgist to the Mines and Mining Department of the Chicago Columbian Fair, and was later employed at the Guggenheim works at Perth Amboy, N. J. As triangulator for the U. S. Geological Survey in 1897, he had charge of a party to survey the Montana timber reserves. Soon after the declaration of war with Spain, Mr. Ulke was appointed Assistant Inspector of Ordnance, U. S. A., which position he resigned in 1900 to become metallurgical engineer to the Lake Superior Power Co., Sault Ste. Marie, Ont. Mr. Ulke has contributed to the present volume the papers, "Progress in the Electrolytic Refining of Copper in 1901." and "Progress in the Metallurgy of Nickel."

WATSON, JOHN R., was educated at Bolton High School, Lancashire, at Manchester Technical School and at Normal School of Science, London. For nine years he was employed by Brunner Mond & Co., in England, as engineer, and in 1893-94 he remodeled the plant of the Fords Alkali Co., the bicarbonate plant at Natrona, Pa., and the Diamond soda plant at Milwaukee, Wis. Mr. Watson at present is employed as engineer for the Lake Superior Power Co., and has made a special study of the design of chemical machinery, used in the heavy chemical industry, Mond gas producers, Semet-Solvay coke ovens, ammonia plants and sulphite-pulp machinery. To the present volume Mr. Watson contributes the illustrated article, "An Improved Ammonium Chloride Distiller for a 100-Ton Soda Ash Plant."

WEED, WALTER HARVEY, was born in St. Louis, Mo., May 1, 1862, and was graduated in 1883 from Columbia College School of Mines in the course of mining engineering. Mr. Weed was appointed assistant geologist U. S. Geological Survey in June, 1883; in 1885 discovered the vegetable origin of the siliceous sinter of Yellowstone; and the following year discovered and described Death Gulch, Yellowstone Park. Following his specialty of economic and applied geology, Mr. Weed has investigated and reported on various coal, gold and silver districts of Montana, and has made careful studies of the copper and gold regions of Virginia and the Carolinas, Cripple Creek district, and others in Colorado, Arizona, California, Wyoming and Mexico. To the present volume Mr. Weed contributes the monograph, "Montana Sapphires" and the reviews of progress of copper mining in North Carolina and Virginia.

WELLS, JAMES S. C., was graduated from Columbia College (now Columbia University) School of Mines, in 1875, in the chemistry course, and later was given the degree of Ph.D. by that institution. From 1875 to 1879 he was assistant in quantitative analysis, and from 1879 to the present time he has filled the position of instructor in analytical chemistry at Columbia University. During this time he has also engaged in other professional work as a chemist, metallurgist, and mine examiner. Dr. Wells has written numerous articles for scientific journals, and for this volume he has contributed the "Review of Progress in the Cyanide Process during 1901."

WILKENS, H. A. J., was graduated in 1887 as a mining engineer from Lehigh University, Bethlehem, Pa., and during 1889 studied at the Royal School of Mines, at Freiberg, Saxony. His first professional work was performed for the Lehigh Zinc & Iron Co., at South Bethlehem, Pa., later for the Empire Zinc Co., at Joplin, Mo. During the year 1890 Mr. Wilkens was in charge of the operations of the Gold King Mining Co., of San Diego County, Cal., and from 1891 to 1895 acted as mining engineer in charge of the Franklin Lehigh Zinc & Iron Co., at Franklin Furnace, N. J. In 1895 he became general manager of the Wetherill Concentrating Co., continuing in this capacity until the company's patents were sold in 1897. At present Mr. Wilkens is consulting engineer for the Wetherill Separating Co., and manager of the acid and mining departments of the New Jersey Zinc Co. He contributes to the present volume the monograph, "Recent Progress in the Wetherill System of Magnetic Concentration."

## INTRODUCTION.

---

THE total value at the place of production of the mineral and metal output from both domestic and foreign ores and bullion of the United States in 1901 was \$1,372,826,102, as compared with \$1,369,256,563 in 1900, a gain of \$3,569,539 for the year.

Of these vast sums, which are without precedent in the history of the mineral industry, ores and minerals contributed \$723,348,715 in 1901 and \$672,090,416 in 1900; metals, \$490,279,923 in 1901 and \$524,432,533 in 1900; secondary products, \$73,068,974 in 1901 and \$76,372,375 in 1900; while the value of metals smelted or refined from foreign material was \$86,128,490 in 1901 and \$96,364,939 in 1900. In these gross totals of value are included certain duplications, such as those of the manganese and iron ore used in making ferromanganese and pig iron; bauxite used in making aluminum and alum; coal used in making coke; lead used in making white and red lead and litharge and a few other duplications, the whole amounting in 1901 to \$93,629,061 and in 1900 to \$116,768,662. Deducting these amounts and also the values of the crude foreign ores or metals smelted or refined here, the net value of the mineral industry of the United States was \$1,193,068,461 in 1901, and \$1,156,126,662 in 1900.

In the preparation of the statistics for this volume, the figures previously reported for 1900 have been revised in the light of later and more minute investigation, in accordance with our practice, wherefore it is important for students to observe the caution to use always the figures in the latest volume of *THE MINERAL INDUSTRY*. There are no statistical reports of this nature which are absolutely correct, owing to the practical impossibility of obtaining accurate reports from all the producers in some extensive and greatly subdivided industries, the absence of records on the part of many producers which prevents them from making returns, the unwillingness of a few to give their figures, and confusion as to the stage in which many products are to be reported. The last difficulty is especially likely to lead to errors in values, some producers estimating the worth of their product at the pit's mouth, and others reporting it in a more or less advanced state of completion, including thus not only the cost of carriage, but also the cost of manipulation. These difficulties appear not only in our own statistics, but also in the statistics reported by various governments. In our own work, however, we make a practice of going backward and correcting figures previously reported, whenever mistakes are discovered by subsequent investigation.

For the greater part of the statistics relating to the domestic production of the United States during 1901 we have been indebted to Department of Mineral Resources of the United States Geological Survey, and for the production of gold and silver in the United States during 1901 to Mr. George E. Roberts, Director of the Mint. Special acknowledgment is due to both of these departments for their active and hearty co-operation.

We have made great use of the reports of several State geological surveys,

especially those of Alabama, Kansas, Iowa and Montana, and the State mining bureaus of California and Colorado. We have generally credited these figures to the proper sources in the subsequent pages, but this acknowledgment may stand for any unintentional oversights.

PRODUCTION OF ORES AND MINERALS IN THE UNITED STATES. (FIRST PRODUCTS.)

In using the statistics in the foregoing tables reference should also be made to the detailed tables under the respective captions further on in this volume, where many explanatory notes as to the statistics will be found. The following notes refer to the four preceding tables: (a) Except where otherwise specified. (b) Not enumerated. (c) Crude mineral. Nominal value for 1900. In 1901 includes 5,344 short tons of refined borax, valued at \$697,907. (d) Partly estimated. (e) Estimated. (f) Includes by-product production. (g) Barrels of 300 lb. (h) Barrels of 400 lb. (i) Includes manganese iron ore; this is not duplicated in the

report of iron ore. (j) Value per square, i.e., 100 sq. ft., lapped and laid; the weights are calculated on the basis 8 squares = 2,000 lb., but these figures are only approximately correct. (k) Kilograms or per kilogram. (l) Reduced to a basis of 66° B. (m) Average market price at New York. (n) Nominal. (o) Value before grinding. (p) Includes ochre,umber, sienna, and oxide of iron. (q) Includes salt used for the manufacture of alkali; the barrel of salt weighs 280 lb. (r) Reduced to a basis of 55% ash. (s) Includes a small amount made from spelter. (t) Average value of Lake copper at New York, less 0.25c. per lb. (u) Includes spiegeleisen, though the total value is reckoned as if the whole product were ferromanganese. (v) Average market price at Pittsburgh. (w) Troy oz. (x) Flasks of 75.5 lb. (y) Barrels of 42 gal. (z) Includes a comparatively small amount made directly from ores. (aa) Not included in the preceding tables. (bb) Does not include 40,000 pieces of unspecified weight; the value, however, is included in the total. (cc) Included with common talc. (dd) Includes tripoli. (ee) Included with diatomaceous earth. (ff) Included with bituminous.

Abbreviations: Sh. T., short tons (2,000 lb.); L. T., long tons (2,240 lb.); M. T., metric tons (2,204.6 lb.).

#### METALS AND ALLOYS.

**Aluminum.**—The production of aluminum in the United States in 1901 was 7,150,000 lb. (\$2,238,000), as compared with 7,150,000 lb. (\$2,288,000) in 1900.

**Antimony.**—The production of antimony in the United States in 1901 was 5,298,000 lb. (\$542,000), as compared with 3,200,000 lb. (\$301,440) in 1900.

**Copper.**—The production decreased from 600,832,505 lb. (\$97,755,449) to 597,443,212 lb. (\$86,639,266) in 1901. The main increases were in Utah, California, Arizona and Lake Superior. Montana fell off considerably. In addition to the domestic copper produced in 1901, there were 102,645,963 lb. (\$16,536,265) derived from foreign sources.

**Ferromanganese.**—The production of ferromanganese, including spiegeleisen, was 291,461 long tons (\$16,589,960), as compared with 255,977 long tons (\$22,825,469) in 1900.

**Ferromolybdenum.**—The production in 1901 was 16,000 lb. (\$19,600), as compared with 11,000 lb. (\$12,100) in 1900.

**Gold and Silver.**—The domestic production of gold in 1901 was 3,880,578 troy oz. (\$80,218,800), as compared with 3,781,310 troy oz. (78,159,674) in 1900. The production of silver was 59,653,788 troy oz. (\$35,165,902), as compared with 59,561,797 troy oz. (\$36,576,900). Colorado's production of gold increased, principally due to Cripple Creek. South Dakota, California and Alaska, including Cape Nome and the American Yukon, also contributed to the increased production. Besides the production reported, 1,730,856 oz. of gold and 45,410,085 oz. of silver were smelted in the United States from imported ores. The average value of silver in the United States in 1901 was 58.95c. per oz., against 61.33c. per oz. in 1900.

**Iron.**—The production of pig iron in 1901, exclusive of ferromanganese and spiegeleisen, was 15,586,893 long tons (\$232,800,328), as compared with 13,533,265 long tons (\$250,184,857) in 1900. Of the production in 1901 9,546,793 long tons were Bessemer pig, against 7,943,452 long tons in 1900. Basic pig increased from 1,072,376 to 1,448,850 long tons. The remainder of the output is classed as foundry and forge iron.

**Lead.**—The domestic production in 1901 was 270,700 short tons (\$23,280,200), against 275,907 short tons (\$24,114,272) in 1900. The decrease was due largely to the restriction of output by the Idaho mines. The average price of lead at New York in 1901 was 4.334c., against 4.37c. per lb. in 1900. Besides the above, the American smelters in 1901 recovered 22,260 tons of lead from foreign ore and base bullion, against 103,341 tons in 1900.

**Molybdenum.**—Some 35,000 lb. of molybdenum (\$62,125) were produced in 1901, as compared with 32,000 lb. (\$46,080) in 1900. A considerable portion of the ore came from Arizona.

*Nickel.*—The domestic production of nickel was 6,700 lb. (\$3,551), as compared with 9,715 lb. (\$4,534) in 1900.

*Platinum.*—There was a production of 1,408 troy oz. (\$27,526) of platinum from domestic ores in 1901, as compared with 173 oz. (\$3,114) in 1900. The value of bar platinum at New York in 1901 averaged \$19.55 per oz.

*Quicksilver.*—The production of quicksilver increased from 27,855 flasks (\$1,288,851) to 29,727 flasks (\$1,382,305) in 1901. Texas contributed 400 flasks to the total and Oregon 75 flasks.

*Tungsten.*—The production was 75,000 lb. (\$45,750) in 1901, against 57,000 lb. (\$51,800) in 1900. The production of ferrotungsten in 1901 was 13,000 lb. (\$3,770).

*Zinc.*—The production in 1901 was 140,822 short tons (\$11,265,760), as compared with 123,231 short tons (\$10,819,682) in 1900. Missouri and Kansas increased their production. The average price of spelter in New York in 1901 decreased to 4.08c. per lb., against 4.39c. per lb. in 1900.

#### ORES, MINERALS AND CHEMICAL PRODUCTS.

*Alum and Aluminum Sulphate.*—The production of crystallized alum in the United States in 1901 was 7.755 short tons (\$208,846), as compared with 20,531 short tons (\$615,930) in 1900. The production of aluminum sulphate in 1901 was 74,721 short tons (\$1,355,720), as compared with 61,678 short tons (\$1,480,272) in 1900.

*Ammonium Sulphate.*—The amount of ammonium sulphate recovered in the United States in 1901 was 60,000 metric tons (\$3,665,400) as compared with 58,000 metric tons (\$3,651,680) in 1900. The value of sulphate, basis 25%, was \$61.09 per metric ton at New York in 1901, against \$62.96 in 1900.

*Asbestos.*—The domestic production was 747 short tons (\$13,498) in 1901, as compared with 1,100 short tons (\$16,500) in 1900. In each year the production was made almost entirely by one mine in Georgia.

*Asphaltum and Asphaltum Products.*—The production of asphaltum, liquid and solid, in 1901 was 21,916 short tons (\$383,359), as compared with 11,140 short tons (\$218,520) in 1900, the output coming from California and Indian Territory. California and Kentucky, chiefly the former, produced 34,248 short tons (\$138,601) of bituminous rock in 1901, as compared with 34,277 short tons (\$138,892) in 1900. Utah and the Indian Territory produced 6,970 short tons (\$33,375) of asphaltic limestone, as compared with 3,910 short tons (\$16,830) in 1900. The output of Utah increased in 1901, while that of the Indian Territory showed a small decrease. The production of grahamite or gilsonite in 1901 was 1,500 short tons, as compared with 3,279 short tons in 1900.

*Barytes.*—The production in 1901 was 49,070 short tons (\$157,844), as compared with 41,466 short tons (\$161,717) in 1900. Of the production in 1900 Missouri furnished the larger output, the remainder being obtained in Virginia, Tennessee, North Carolina and Georgia.

*Bauxite.*—The production in 1901 was 18,905 long tons (\$79,914), as compared with 23,445 long tons (\$85,922) in 1900.

*Bromine.*—The production in 1901 was 552.023 lb. (\$149,045), against

521,444 lb. (\$140,790) in 1900. These figures include the bromine equivalent of potassium bromide which is produced in Michigan.

*Calcium Borate.*—The production in 1901 was 23,231 short tons, as compared with 25,350 short tons in 1900. Most of this product is colemanite, mined in California. The year 1901 was notable for the greatly increased prices per short ton, which were \$43.57, as compared with \$21 in 1900.

*Carborundum.*—The production reported by the sole producer was 3,838,175 lb. (\$345,435) in 1901, as compared with 2,401,000 lb. (\$216,090) in 1900.

*Cement.*—The total production of Portland cement in 1901 was 12,711,225 bbl. of 400 lb., valued at \$12,532,360, as compared with 7,991,639 bbl. (\$10,461,910) in 1900. The Lehigh district of Pennsylvania and New Jersey has maintained its supremacy as a center of production, and Michigan, and other States also showed important gains. Aside from the remarkable increase in production, the year 1901 was notable for the very low prices commanded by cement in the Eastern markets. The production of natural rock cement in 1901 was 7,084,823 bbl. of 300 lb., valued at \$3,056,278, as compared with 9,177,222 bbl. (\$4,308,709) in 1900. The Kentucky-Indiana district increased its output, but other parts of the United States showed a falling off owing to the competition with Portland cement. The production of slag cement in 1901 was 272,689 bbl. of 400 lb., valued at \$346,430, against 490,150 bbl. (\$216,090) in 1900.

*Chrome Ore.*—The production in 1901 was 368 long tons (\$5,790), with no production for 1900. The entire production during 1901 was mined in California.

*Clay.*—The value of brick and other clay products made in the United States in 1901 was \$110,211,587, as compared with \$78,704,678 in the previous year.

*Coal and Coke.*—The total production of coal in the United States in 1901 was 292,340,758 short tons (\$348,813,831), as compared with 268,315,433 short tons (\$322,521,530) in 1900. The production of anthracite, all of it from Pennsylvania with the exception of an insignificant amount from Colorado, was 67,471,667 short tons (\$112,504,020) in 1901, as compared with 57,464,235 short tons (\$102,972,596) in 1900. Kentucky's production of cannel coal in 1901 is included under bituminous; the production in 1900 was 29,471 short tons (\$88,413). The output of bituminous coal, of which Pennsylvania and the Central States are the largest producers, was 224,869,091 short tons (\$236,309,811) in 1901, as compared with 210,821,727 (\$219,460,521) in 1900. There was an increase in the output of all of the important coal-producing States in 1901. The total production of coke in 1901 was 21,789,945 short tons (\$44,431,522), as compared with 19,206,994 short tons (\$50,272,050) in 1900. Pennsylvania furnished about two-thirds of the output each year.

*Cobalt Oxide.*—The production of cobalt oxide in 1901 was 13,360 lb., as compared with 12,270 lb. in 1900.

*Copperas.*—The production in 1901 was 23,586 short tons (\$112,366), as compared with 12,374 short tons (\$96,517) in 1900. The chief producer in this country is the United States Steel Corporation, which controls all the wire and rod works recovering copperas as a by-product. The above statistics do not include

copperas converted into Venetian and Indian reds at the works of original production.

*Copper Sulphate.*—The production in 1901 was 78,004,257 lb., as compared with 78,218,478 lb. in 1900. Of this the amount recovered as a by-product, chiefly by gold and silver refiners, was 51,000,000 lb. in 1901 and 44,368,478 lb. in 1900. The remainder of the output each year was made from metallic copper previously reported in the production of that metal. The average value of copper sulphate at New York per 100 lb. was \$4.71 in 1901, as compared with \$4.99 in 1900.

*Corundum and Emery.*—The production of corundum and emery in 1901 was 4,305 short tons (\$146,040), as compared with 830 short tons (\$58,100) of corundum, and 4,200 short tons (\$189,000) of emery in 1900. The production of steel emery or crushed steel in 1901 was 690,000 lb. (\$37,950), against 690,000 lb. (\$48,300) in 1900, the entire make each year being supplied by the Pittsburg Crushed Steel Co.

*Feldspar.*—The production in 1901 was 31,019 long tons (\$220,422), as compared with 29,447 long tons (\$136,773) in 1900. Pennsylvania, Massachusetts and New York being the chief producers each year.

*Fluorspar.*—The production in 1901 was 19,586 short tons (\$113,803), as compared with 21,656 short tons (\$114,430) in 1900, Illinois and Kentucky furnishing the entire output.

*Fullers Earth.*—The output in 1901 was 10,967 short tons (\$80,697) as compared with 11,813 short tons (\$70,565) in 1900.

*Garnet.*—The production in 1901 was 4,444 short tons (\$158,100), as compared with 3,285 short tons (\$92,801) in 1900, the output each year being furnished by New York, Pennsylvania and Connecticut. The domestic resources of this mineral are large, but the demand for it is limited.

*Graphite.*—The production of crystalline graphite in 1901 was 3,967,612 lb. (\$135,914), as compared with 4,103,052 lb. (\$164,122) in 1900. The production of amorphous graphite in 1901 was 809 short tons (\$31,800), as compared with 1,045 short tons (\$8,640) in 1900. The larger part of the crystalline product in 1900 was obtained from Ticonderoga, N. Y., but a considerable quantity was mined in Pennsylvania, where some of the old mines were reopened. One company produced 2,500,000 lb. (\$119,000) of artificial graphite, as compared with 860,750 lb. (\$68,860) in 1900.

*Gypsum.*—The production increased from 484,202 short tons in 1900 to 659,659 short tons in 1901. These figures represent the amount of crude rock quarried. The larger part of the production is marketed as stucco or plaster of Paris.

*Iron Ore.*—The production in 1901 was 28,887.479 long tons, as compared with 25,917,393 long tons in 1900, these figures being exclusive of the production of manganiferous iron ore, reported separately under manganese. The increase in the production was due chiefly to the Lake Superior ranges, the Southern States showing but a comparatively small gain.

*Lead White, Red Lead and Litharge.*—The production of white lead in 1901 was 100,787 short tons (\$11,252,653), as compared with 96,408 short tons (\$9,910,742) in 1900; of red lead, 13,103 (\$1,448,550), as compared with 10,998

(\$1,050,192); of litharge, 9,460 (\$979,586), as compared with 10,462 (\$1,067,124) of orange mineral, 1,087 (\$224,667), as compared with 825 (\$100,650) in 1900. The larger part of these products is obtained by the corrosion of pig lead, but a small part of the white lead product is made directly from ores.

*Limestone for Iron Flux.*—Iron smelters consumed 8,540,168 long tons in 1901, as compared with 6,790,200 long tons in 1900, the increase being caused by the greater production of pig iron.

*Lithographic Stone.*—Utah produced 40 short tons in 1900, a like amount in 1899. There was no output reported during 1901.

*Magnesite.*—In 1901 California produced 13,172 short tons (\$43,057), as compared with 2,708 short tons (\$11,832) in 1900.

*Manganese Ore.*—The production of manganese ore, including manganiferous iron ore, was 638,795 long tons, as compared with 218,222 long tons in 1900.

*Mica.*—The production of sheet mica in 1901 was 360,060 lb. (\$98,859), as compared with 127,241 lb. (\$82,508) in 1900. The production of scrap mica was 2,165 short tons (\$19,719) in 1901, as compared with 5,417 short tons (\$42,889), the values of scrap mica being reckoned for the product before grinding. Practically the entire production of mica is made in South Dakota, New Hampshire, North Carolina and Nevada.

*Mineral Wool.*—The production in 1901 was 6,272 short tons (\$68,992), as compared with 6,002 short tons (\$60,320) in 1900. A part of this product was made from slag and a part by the fusion of natural rock, the latter being the more valuable.

*Molybdenum Ore.*—This ore was produced in the United States in 1901 to the amount of 15 short tons, valued nominally at \$50 per ton, as compared with 24 short tons, valued at \$50 per ton in 1900.

*Monazite.*—North Carolina produced 748,736 lb. (\$59,262) in 1901, as compared with 908,000 lb. (\$50,680) in 1900.

*Natural Gas.*—The production of natural gas in 1901 is estimated at a value of \$27,067,500, as compared with \$18,500,000 in 1900.

*Ocher and Oxide of Iron Pigments.*—The production of ocher, amber, sienna and natural oxide of iron ground pigment, the last being known commonly as "metallic paint," was 43,036 short tons (\$516,306) in 1901, as compared with 41,917 short tons (\$461,087) in 1900. The values are reckoned nominally at \$11 per ton each year. These products merge into one another so that no satisfactory division of the statistics is possible. Pennsylvania is the largest producer.

*Petroleum.*—The total output in 1901 was 69,389,194 bbl. (\$66,417,335), as compared with 62,538,544 bbl. (\$74,246,582) in 1900. The increase was due to California, Texas and Colorado. The above values are calculated for crude oil at the wells. The average value was considerably lower in 1901 than in the previous year.

*Phosphate Rock.*—The production in 1901 was 1,480,358 long tons (\$5,354,022), as compared with 1,527,711 long tons (\$5,375,956) in 1900. The decrease in 1901 was due to a falling off in the export demand.

*Salt.*—The domestic output of salt decreased from 20,738,729 bbl, in 1900, to 20,566,661 bbl. in 1901.

*Silica.*—The production of vein and dike quartz in 1901 was 34,420 short tons (\$149,298) as compared with 35,915 tons (\$84,400) in 1900. The uses were chiefly in pottery, for packing acid towers, and for grinding for various purposes. The production of grindstones, which are made out of quartzite, or a very hard sandstone, in 1901, amounted to 16,807 short tons (\$165,665) as compared with 42,039 tons (\$482,462) in 1900. The weight of this production of 1901 does not include 40,980 pieces weight not specified but included in the value. The production of oilstones, scythestones and whetstones in 1901 was valued at \$158,300, as compared with \$84,874 in 1900. There was no production of pumice in 1901. The production of diatomaceous earth in the United States in 1901, including tripoli, was 4,020 short tons (\$52,950), as compared with 1,375 short tons (\$9,675) of diatomaceous earth and 1,846 short tons (\$3,987) of tripoli in 1900.

*Slate.*—The production of roofing slate in 1901 was 1,304,379 squares (\$4,114,410) as compared with 990,036 squares (\$2,885,153) in 1900. The production of slate manufactures, chiefly blackboards and structural material, was valued at \$673,115 in 1901, as against \$502,051 in 1900. The production of slate pigment, including Baraga graphite and various kinds of mineral black, was 4,865 short tons, as against 6,617 short tons in the previous year, the values of the products after grinding being respectively \$41,211 and \$72,787.

*Soda.*—The production of soda and soda products from salt, reduced to a common basis of 58% soda ash, was 480,000 metric tons in 1901, as compared with 390,000 metric tons in 1900. The average value of 58% ash at the works was \$17.33 per metric ton, as compared with \$17.95 in 1900. California and Nevada produced 15,000 short tons (\$197,000) of natural soda, basis 58%, in 1901, as compared with 14,100 short tons (\$195,300) in 1900.

*Sulphur and Pyrites.*—Louisiana, Nevada and Utah produced 7,690 long tons of sulphur in 1901, against 4,630 long tons in 1900. The average price of Sicilian seconds at New York in 1901 was \$22.94 per ton, compared with \$22.18 in the previous year. The domestic production of pyrites in 1901 was 234,825 long tons (\$1,024,449), as against 201,317 long tons (\$684,478) in 1900. Virginia was the largest producer each year, Massachusetts ranking second. Sulphuric acid was recovered as a by-product in roasting blende and pyrites, chiefly the former, to the extent of 98,000 short tons, as against 85,000 tons in 1900, the figures being reduced to a common basis of 66°B. Concentrated acid of the latter strength averaged \$23.40 per 2,000 lb. at New York in 1901, as against \$24.07 in 1900.

*Talc and Soapstone.*—The production during 1901 of soapstone for slabs and other manufactured articles and common talc, mostly ground to powder was 28,643 short tons (\$424,888), as compared with 18,956 short tons (\$189,560) of soapstone and 7,770 short tons (\$60,217) of common talc during 1900. This was produced chiefly in North Carolina, New Jersey and Vermont. The production of fibrous talc, nearly all of it from St. Lawrence County, N. Y., was 69,200 short tons (\$483,600), as compared with 45,000 short tons (\$236,250) in 1900.

*Tungsten Ore.*—There was a production in 1901 of 160 long tons of tungsten ore from South Dakota, Colorado and Arizona, with a small amount from Connecticut and New Mexico, which was valued nominally at \$27,720 at the mines. The statistics for 1900 were 220 long tons, valued at \$35,200.

*Uranium Ore.*—In 1901 Colorado produced 375 short tons of uranium ore, estimated at a value of \$102,500, as compared with 153 short tons, valued at \$45,900 in 1900.

*Venetian Red.*—The production of Venetian and Indian reds in 1901 was 9,201 short tons (\$153,467), as compared with 6,352 short tons (\$110,658) in 1900. These figures include only the output at works where the original copperas was made, and do not include any that may have been made by second handlers.

*Zinc Ore.*—The amount of zinc ore of domestic origin exported from the United States in 1901 was 44,156 short tons (\$1,167,684), as compared with 42,062 short tons (\$1,133,663) in 1900. Most of the ore exported was mined in New Jersey, although a considerable portion was shipped from Colorado via New Orleans and Galveston.

*Zinc Sulphate.*—There was a production of zinc sulphate in 1901 of 7,500 short tons, as compared with 527 short tons in 1900.

*Zinc White.*—The production in 1901 was 46,500 short tons, as compared with 47,151 short tons in 1900. The total value was \$3,720,000, as compared with \$3,772,080 in 1900. Nearly all the American production of zinc white is made directly from the Franklinite ores mined in New Jersey.

## ALUMINUM AND ALUM.

UNDER this general caption are grouped aluminum, alum, bauxite, cryolite, corundum and emery, substances which, previous to Volume VII., appeared under individual captions. The present arrangement is a logical one, since both bauxite and cryolite are used as raw material in the manufacture of aluminum and alum, two industries so interwoven that a logical separation is impossible, and, since corundum, though employed mainly as an abrasive, is now used in part as a source of aluminum. In this view aluminum, alum and the aluminum minerals—bauxite and cryolite, corundum and emery—bear the same relation to one another as do copper, copper sulphate or bluestone and copper ores.

### I. BAUXITE.

The production of bauxite in 1901 was 18,905 long tons, valued at \$79,914, being a large falling off from the output of the preceding year. Of the production in 1901, Georgia contributed the largest quantity, followed by Alabama and Arkansas, the last named State producing but 867 long tons. The following companies were in operation during the year: Republic Mining & Milling Co., in Alabama and Georgia; Southern Bauxite Mining & Milling Co., J. H. Hawkins, Harrison Bros., International Aluminum Mining Co., in Georgia; and Southern Bauxite Mining & Milling Co., Pittsburg Reduction Co., and one minor producer in Arkansas. The mines of the Illinois Chemical Co. were inoperative during the year.

Bauxite is consumed chiefly for the manufacture of aluminum, although a large quantity is used in the manufacture of aluminum sulphate and crystallized alum. In order to ascertain the annual consumption of bauxite and its value in the United States during the past five years the following table has been compiled which includes total production, imports, exports and consumption, with the respective values of each.

PRODUCTION, IMPORTS, EXPORTS, AND CONSUMPTION OF BAUXITE IN THE  
UNITED STATES.

| Year.  | Production. |           |            |          |          | Imports.  |          | Exports.  |         | Consumption. |          |
|--------|-------------|-----------|------------|----------|----------|-----------|----------|-----------|---------|--------------|----------|
|        | Alabama.    | Georgia.  | Total. (a) |          |          |           |          |           |         |              |          |
|        | Lg. Tons.   | Lg. Tons. | Lg. Tons.  | Value.   | Per Ton. | Lg. Tons. | Value.   | Lg. Tons. | Value.  | Lg. Tons.    | Value.   |
| 1897.. | 18,088      | 7,507     | 20,590     | \$51,475 | \$2.50   | 2,645     | \$10,515 | 2,537     | \$5,074 | 20,708       | \$56,916 |
| 1898.. | 13,948      | 12,948    | 26,791     | 66,978   | 2.50     | 1,201     | 4,238    | 1,000     | 2,000   | 26,992       | 69,216   |
| 1899.. | 14,144      | 19,619    | 36,813     | 101,285  | 2.75     | 6,666     | 23,768   | 2,030     | 4,567   | 41,449       | 120,436  |
| 1900.. | 650         | 20,715    | 23,445     | 85,922   | 3.66     | 8,656     | 32,967   | 1,000     | 3,000   | 31,101       | 115,880  |
| 1901.. | 18,088      |           | 18,905     | 79,914   | 4.23     | 18,313    | 66,107   | 1,000     | 3,000   | 36,218       | 144,021  |

(a) Arkansas produced 3,050 long tons in 1899, 2,080 long tons in 1900, and 867 long tons in 1901, which are included in the totals for those years.

*Alabama and Georgia.*—(By Thomas L. Watson.)—The Southern Appalachian bauxite deposits are located in northwest Georgia and the adjacent portion of Alabama, and are limited to the central and southeastern portions of the Coosa valley, extending from Adairsville, Ga., southwestward to near Jacksonville, Ala., a distance of about 60 miles, occupying portions of Bartow, Floyd, Polk, Walker, Chattooga and Gordon counties, in Georgia, and of Cherokee, Cleburne and Calhoun counties in Alabama. The deposits are irregularly distributed over the area, and are grouped about certain centers or along certain lines of fracture forming four groups as follows: The Hermitage district, including portions of Bartow and Floyd counties; the Bobo district, including portions of Floyd and Polk counties; the Summerville district, including portions of Chattooga and Walker counties, in Georgia; and the Dykes' district in Cherokee County, Ala. Several single isolated deposits are found outside the limits of the districts in Georgia, but they have not as yet been worked.

The bauxite deposits are associated with the Knox dolomite, which is a gray crystalline magnesian limestone between 4,000 and 5,000 ft. in thickness and contains an abundance of chert in the form of lens and small nodules. It is part Cambrian and part Lower Silurian (Ordovician) in age. The bauxite occurs as distinct pocket deposits of variable size, the largest of which yield several hundred tons of the ore. They differ from the Arkansas and some foreign deposits in not being stratified; and from certain other accumulations of bauxite in not occurring as an alteration or residual product derived from the decay or other change of pre-existing rock. No rocks of igneous origin are found within the limits of the Georgia-Alabama bauxite area. The ore bodies are definitely connected with the numerous fault lines of the region, and as such the ore bodies are believed to have been formed about vents and springs supplied by the ascending currents of percolating water along the lines of breakage. The alumina has been derived from the great thickness of the immediately underlying middle Cambrian aluminous shales. On physiographic grounds, the age of the Southern Appalachian bauxite deposits is fixed near the close of the Eocene. In the early history of mining in this field, the output from Alabama greatly exceeded that from Georgia, and previous to the working of the Arkansas bauxite deposits in 1899, the entire production in America was from the Georgia-Alabama area. The greater part of the bauxite mined in Georgia and Alabama is used in the manufacture of alum, only a small percentage of the whole being utilized in the manufacture of the metal aluminum. The first grade ore brings \$5.50 and the second grade \$4.50 per long ton.

*Arkansas.*—The bauxite deposits are confined chiefly to two districts, one a small area south of Little Rock, about 20 miles long and 5 or 6 miles wide, lying in eastern Pulaski County and northern Saline County, the other and more important embracing about 12 square miles in Bryant township. Between these districts are several isolated deposits. In thickness the bauxite bed varies up to 40 ft., the average being between 10 and 15 ft. The greatest thickness—30 ft.—occurs in section 16. The best grade of bauxite produced is the granite variety containing less than 3%  $\text{SiO}_2$  and very little iron except that which can be removed by hand washing.

The Pittsburg Reduction Co. is erecting an extensive mining plant at Bauxite, Saline County, which is expected to be in operation in the latter part of 1902. The production of bauxite from Arkansas will be greatly increased by the output from the new works.

*California.*—A large deposit of disintegrated rock containing free alumina, has been discovered in California,<sup>1</sup> containing from 31 to 35%  $\text{Al}_2\text{O}_3$ , together with  $\text{FeO}$ ,  $\text{MgO}$ , and  $\text{SiO}_2$ . The ore is stated to be associated with quartz ledges assaying from \$2 to \$39 per ton in gold, and the two minerals may therefore be worked together. While the large beds of purer bauxite remain unexhausted in Florida, it is doubtful however whether the Californian deposits will be drawn upon, as they are situated 17 miles from the nearest point on the Southern Pacific Railroad. With regard to the methods of treating bauxite for extraction of the alumina in a form which can be used in the electrolytic baths, Hall has secured three American patents. The details of these patents are given elsewhere in this section under the caption *Production*. The new process may have a very important effect upon the future of aluminum, if, as the inventor evidently hopes, it can be carried out more cheaply than the present method of preparing the refined alumina. By the latter, the cost of the alumina represents 30% of the total cost of manufacturing aluminum of the higher grades. The following estimate of itemized cost per pound of aluminum produced, was published by the late Capt. Hunt some years ago, and is still fairly correct:—

Energy, 5c.; alumina, 6c.; electrodes, 2c.; chemicals and stores, 1c.; labor and superintendence, 3c.; interest and maintenance, 3c.; total cost, 20c.

A process which would cut down the cost of the refined alumina to 2c. per lb. would therefore make it possible for aluminum to be sold at 20 to 24c. per lb. and would have a notable effect in extending the utilization of the light metal, in the arts and industries.

*Imports and Exports.*—There was an unusually large importation of French bauxite during 1901, which amounted to 18,313 long tons valued at \$66,107, as compared with 8,656 long tons valued at \$32,967, in 1900. This increase was due mainly to the low ocean freight rate of an average of \$2.25 per long ton from foreign ports, which, with the import duty of \$1 per long ton, permitted the delivery from the south of France at New York, Philadelphia, and Baltimore at a lower rate per ton than it cost to ship by rail from Georgia or Alabama. The high iron content of the French bauxite prevents its use for the manufacture of aluminum sulphate, and it is consumed mainly in making aluminum hydrate, which is used as a raw material for the manufacture of aluminum. The exports of bauxite during 1901 were 1,000 long tons, valued at \$3,000.

The world's supply of bauxite is derived chiefly from France, Ireland, and the United States, the production from 1894 to 1900, inclusive, being given in the subjoined table:—

---

<sup>1</sup> *Electricity* (New York), Sept. 18, 1901.

## PRODUCTION OF BAUXITE IN THE PRINCIPAL COUNTRIES. (IN METRIC TONS.)

| Country.            | 1894.  | 1895.  | 1896.  | 1897.  | 1898.  | 1899.  | 1900.  |
|---------------------|--------|--------|--------|--------|--------|--------|--------|
| France.....         | 26,032 | 17,958 | 33,620 | 41,740 | 36,723 | 48,215 | 55,530 |

*Italy.*—(By Giovanni Aichino.)—The recently discovered deposits of bauxite are situated in the central part of the Apennine Mountains, the most important being at Lecchi né Marsi, on the slopes of Monte Turchio; the nearest railway station is Pescina, on the Roma-Sulmona line. The deposit is at least 250 acres in extent, and averages from 3 to 10 ft. in thickness. The ore is brownish-red to reddish-white in color, and is more or less compact, sometimes being earthy.

The following analyses of bauxite have been reported from the laboratory of the Royal Board of Mines, Geological Survey. Specimens Nos. 1 to 5, inclusive, are from Lecchi né Marsi, and No. 6 from Petraraja. Analyses Nos. 1 to 4 were made by G. Aichino, and Nos. 5 and 6 by E. Mattiolo.

Details of the progress in the purification of bauxite will be found under the caption "Aluminum," elsewhere in this section.

## II. CORUNDUM AND EMERY.

The production of corundum and emery and the imports of emery in recent years are given in the subjoined tables:—

## PRODUCTION OF CORUNDUM AND EMERY IN THE UNITED STATES. (a)

| Substance.        | 1898.        |           |             | 1899.        |           |             | 1900.        |           |             | 1901.        |           |             |
|-------------------|--------------|-----------|-------------|--------------|-----------|-------------|--------------|-----------|-------------|--------------|-----------|-------------|
|                   | Tons.<br>(b) | Value.    | Per<br>Ton. | Tons.<br>(b) | Value.    | Per<br>Ton. | Tons.<br>(b) | Value.    | Per<br>Ton. | Tons.<br>(b) | Value.    | Per<br>Ton. |
| Corundum .....    | 786          | \$63,630  | \$80.96     | 970          | \$78,570  | \$81.00     | 880          | \$58,100  | \$70.00     | 4,305        | \$146,040 | \$37.40     |
| Emery .....       | 2,936        | c 143,800 | 48.65       | 3,000        | 150,000   | 50.00       | 4,900        | 189,000   | 45.00       |              |           |             |
| Steel emery ..... | 330          | 46,900    | 140.00      | 337          | 47,250    | 140.21      | 345          | 48,300    | 140.00      | 355          | 49,700    | 140.00      |
| Total .....       | 4,072        | \$253,680 |             | 4,237        | \$275,820 |             | 5,375        | \$395,400 |             | 4,660        | \$195,740 |             |

(a) The values are based on the prices at the mines, but except in the case of steel emery are of slight significance owing to the great range between the different grades of the minerals. The changes in the annual averages do not indicate fluctuations in market quotations so much as changes in the proportion of different grades of mineral in the total. (b) 2,000 lb. (c) More or less nominal.

## PROGRESS OF THE CORUNDUM AND EMERY INDUSTRY DURING 1901.

BY JOSEPH HYDE PRATT.

Two noteworthy changes have been made in the corundum industry during 1901; one, the manufacture of an artificial corundum by the electric furnace treatment of bauxite and the other, the development of the recently discovered corundum deposits 25 miles southwest of Roseman, Gallatin County, Mont.

In the Montana deposits the corundum occurs in grains and crystals, from minute particles to a size 2 in. and more in length and 1 in. in width. Mill tests by Mr. L. S. Ropes of the Montana Corundum Co. have shown about 20% mineral in the rock and tests on the finished product indicate that it has a very good abrasive efficiency. The corundum is readily cleaned, affording a high-grade commercial product, and a complete plant is being installed for treating the ore and preparing the product for the market. The corundum mined by the Canada Corundum Co. at the Craig mine, Raglan township, Ontario, which occurs somewhat similar to the Montana deposits, is now quoted on the market. Recent tests<sup>1</sup> of the commercial product from this mine, show that it is a satisfactory abrasive, and indicate that the superficial alteration observed on the corundum first obtained is disappearing as mining is carried deeper. The ore occurs in syenite, and as is also the case with the Montana ores, both orthoclase and biotite have to be removed in the cleaning process. The Canadian and Mon-

<sup>1</sup> Private communications.

tana deposits are very extensive and if the present price of corundum of 8@10c. per lb. is maintained the product should be marketed in quantity at a fair profit.

In the Southern fields, development is continued of the corundum ore occurring in the bands of gneiss near the summit of the Blue Ridge in Clay County, N. C., and the adjoining Towns County, Ga. During 1901 these deposits produced considerable corundum but it is yet too early to state definitely to what extent they can be operated. The garnet associated with the ore has to be separated before the best commercial corundum can be attained and the low percentage of corundum in the rock is a factor which increases the cost of production. With one exception the large corundum mines now owned by the International Emery & Corundum Co. in Macon and Clay counties, N. C., and Rabun County, Ga., were idle, while the Corundum Hill mine, at Callasaja, Macon County, N. C., was operated to a small extent throughout the year. Large deposits of corundum occur in these properties which are capable of producing the best quality corundum in quantity. The Toxaway Co., of Sapphire, N. C., owning a large tract of land in southwestern Transylvania and southeastern Jackson counties, has done a little development work on the mine formerly operated by the Sapphire Valley Corundum Co. and a number of promising deposits of corundum were exposed. The North Carolina Corundum Co. is opening a mine at Buck Creek, Clay County, adjoining the property of the International Corundum Co. The corundum is said to occur in quantity. The National Abrasive Manufacturing Co., owning deposits in Jackson and Macon counties, N. C., has not operated them recently but has confined its attention to the production of garnet from Sugar Loaf Mountain, Jackson County.

The development of the new corundum deposits and the known occurrence of this mineral in quantity should supply the full demand of the domestic market. Including imports, about 16,000 tons of corundum and emery are consumed annually in the United States and of this 500 tons are corundum. At the present price of 8@10c. per pound for corundum a small quantity only will be called for, but with a slight decrease in price a greater demand will arise at the expense of the emery. A small amount of corundum is imported into the United States from India but not enough to make any material difference in home production, and with an increased domestic output of corundum of good quality it is probable that importation would cease.

What effect the manufacture of artificial corundum from bauxite by the Norton Emery Wheel Co. will have on the production of corundum, cannot yet be told, but much depends upon the question of cost. This company has erected a large plant at Niagara Falls, N. Y., and a portion of its output will be placed on the market.

In the emery field, the Chester mines have been purchased by the Ashland Emery & Corundum Co. and the Hampden Emery Wheel Co. has entered the Peekskill emery field as a producer. The Chester emery still retains its high quality and is often designated as a corundum. The Peekskill emery, while not showing as high an abrasive efficiency as the Chester emery, possesses good abrasive qualities and for some purposes is fully as satisfactory as the best Chester emery or corundum. The spinel, which replaces the larger proportion

of corundum in this ore, has a good cutting edge and breaks with a rough fracture. This product gives good satisfaction when made into a vitrified wheel. A large increase in the production of Peekskill emery is anticipated and when thoroughly cleaned and prepared it should replace much of the imported ore. If the emery contaminated with garnet is kept separate, there should be no difficulty in obtaining a product which when cleaned can be manufactured into a vitrified wheel. A large quantity of crude Turkish and Naxos emery ores continues to be imported into the United States, due primarily to the low price at which it can be placed on the docks at Boston, New York or Philadelphia, as it is brought over as ballast. These imports amount to nearly 12,000 tons per year and the total domestic consumption barely exceeds 16,000 tons. There is thus ample opportunity for a decided increase in the production of emery in this country to replace at least a portion of that imported. This may be said of corundum also, for with a production of 1,000 or 1,500 tons a similar amount of emery would be replaced and even with a slight decrease in price of the corundum, a much larger quantity would be used.

The demand for corundum and emery is increasing, due to the large increase in general manufacturing, as well as to the improved methods of making the many varieties of corundum and emery stones and wheels, as oilstones, scythe-stones, hones, etc. Emery wheels of larger size are now made and in the near future they will probably rival some of the larger grindstones. These large emery wheels are made entirely by the silicate process and are used for saw gummers. It is a question whether the large vitrified emery wheels could be made cheaply enough to compete with large grindstones. Furthermore, many of the purposes for which these larger grindstones are used require a slower cutting than emery would give. Smaller grindstones, especially for household purposes, are being replaced by corundum and emery wheels which are manufactured in considerable quantity. There is no apparent reason why an export trade of American corundum should not be developed as none is produced elsewhere, except a very small quantity in India. The Canadian product would be on equal terms with that of the United States.

The cleaning of corundum ores is now done by an automatic system. The Southern corundum, and emery calls for a somewhat different process than that applied to the Canadian and Montana ores; with the Montana ore a larger proportion of the impurities are removed by concentrators as the corundum is more readily separated from the other minerals in the crushing. It is necessary however to eliminate as much of the feldspar as possible, otherwise the material will fuse and the abrasive efficiency of the vitrified wheel be lessened. Where the mineral attached to the particles of corundum is more or less micaceous it can only be removed by the "Muller process," in which one grain of corundum is made to grind against another and thus wear away the softer material.

In determining the percentage of corundum in an ore the mistake is still being made of reckoning the total percentage of alumina ( $\text{Al}_2\text{O}_3$ ) in the sample as corundum. This is incorrect, as many impurities contain high percentages of alumina. Garnets contain about 20%  $\text{Al}_2\text{O}_3$  and as they have often been mistaken for corundum, considerable care should be taken in examining the sample.

The following method of determining the percentage of corundum in an ore as used by Pratt & Boltwood, of New Haven, Conn., has thus far proved satisfactory. The material is crushed in an iron mortar to pass through a 14-mesh sieve and sampled; 2 g. of the sample are taken and treated with concentrated hydrochloric acid on the water bath for two hours. The residue is then filtered, dried, and fused one-half hour with 6 g. sodium carbonate mixture (two parts  $\text{Na}_2\text{CO}_3$ , one part  $\text{K}_2\text{CO}_3$ ) in a platinum crucible over an ordinary Bunsen burner. The fused mass is extracted with hot water and the solution decanted through a filter. The filter paper is dried and ignited in a platinum dish, the residue from treatment with hydrochloric acid is added to the dish, and the whole treated with an excess of concentrated hydrofluoric acid. The excess of hydrofluoric acid is removed by evaporation on the water bath and the residue is treated with hot water, and finally transferred to an ashless filter paper which with its contents is dried, transferred to a weighed platinum crucible, ignited, cooled and weighed. The increase in weight (residue) is calculated as pure corundum.

There has been practically no change in the uses of corundum and emery for the manufacture of wheels, blocks, stones of various shapes and sizes, emery paper and grains or powder, although there has been some change in the shape of the blocks and stones. Where corundum is transparent it is used for cutting into gems. The artificial abrasives, carborundum and crushed steel, have not cut into the corundum and emery trade to any considerable extent as, so far, they are filling particular fields of their own. However, should corundum be produced in much larger quantities, carborundum will be one of its strongest competitors. With emery, carborundum has been a competitor, but on account of the greater cost of the carborundum, it has not thus far made much inroad on the emery trade. Crushed steel, which is used in the stone cutting trade, particularly for marble and granite, has a field that is not entered by either corundum or emery.

The Ashland Emery & Corundum Co. was recently incorporated under the laws of New Jersey, with a capital of \$3,000,000. The emery companies taken over are the following: Ashland Mills Emery Co., of Perth Amboy, N. J.; Diamond Mills Emery Co., of Philadelphia; Jackson Mills Emery Co., of Easton, Pa.; Walpole Emery Mills, of South Walpole, Mass.; Hampden Emery Mills, of Chester, Mass.; and the Levant Emery Co. It is stated that the output of the company approximates 12,000 tons of crushed imported emery ore per annum, 5,000 tons of native ore, and 2,000 tons of corundum. The company owns emery mines at Chester, Mass., and at Peekskill, N. Y.

**EMERY.—Greece.**—The Naxos emery is found as masses in limestone, and contains 93.5%  $\text{Al}_2\text{O}_3$ . The deposits are worked by the inhabitants of the communities of Apiranthos and Koronis, who own the mining rights and who sell the product to the Government at a uniform price amounting to \$18.55 per ton. There has been a decided increase in the quantity of Naxos exported during the years 1900 and 1901, due to the facility in the shipping operations at Syra, whereas formerly in Naxos the difficulties of the shippers with laborers, and the danger incurred by the steamers loading in an open roadstead were very great. The quality of the mineral is now of better grade than formerly, although the

price remains the same, being \$20.25 per metric ton, which includes the Government tax of \$1 per ton. The emery as received in Syra is selected for exportation, and does not contain the residue of the small stones and rubbish which formerly was indiscriminately shipped at Naxos. The trade promises to flourish, as 6,023 tons, valued at \$130,000, were exported during 1900, and over 3,000 tons were exported in the first three months of 1901. The quantity exported in 1900 was distributed as follows: 1,760 tons to Hamburg, 1,670 tons to Liverpool, 1,380 tons to Rotterdam, 1,000 tons to Boston, and the remainder to Odessa.

### III. CRYOLITE.

The importations of cryolite into the United States during 1901, as in previous years, were derived from the mines in Greenland, and are given in the subjoined table. These shipments were made by the Pennsylvania Salt Manufacturing Co., of Natrona, Pa., which possesses the exclusive privilege to import this mineral into North and South America. The remainder of the output of the Ivigtut mines is shipped to Copenhagen.

#### IMPORTS OF CRYOLITE INTO THE UNITED STATES FROM 1890 TO 1901, INCLUSIVE. (a)

| Year.  | Long Tons. | Value.   | Year.  | Long Tons. | Value.    | Year.  | Long Tons. | Value.   | Year.  | Long Tons. | Value.   |
|--------|------------|----------|--------|------------|-----------|--------|------------|----------|--------|------------|----------|
| 1890.. | 7,129      | \$95,405 | 1893.. | 9,574      | \$126,688 | 1896.. | 8,009      | \$40,056 | 1899.. | 5,879      | \$78,676 |
| 1891.. | 8,398      | 76,350   | 1894.. | 10,684     | 142,494   | 1897.. | 10,115     | 135,114  | 1900.. | 5,437      | 72,763   |
| 1892.. | 7,241      | 26,932   | 1895.. | 9,425      | 125,368   | 1898.. | 6,201      | 88,501   | 1901.. | 5,383      | 70,886   |

(a) The values are those reported by the Custom House and represent the estimated cost at the mines. There being no United States Consul at shipping point in Greenland, a *pro forma* invoice is prepared for Custom House purposes, wherein the value represents only a small part of the actual cost at buyers' factory.

The value of cryolite in the United States is stated to be \$80 per ton of 2,240 lb., and results from the following items: Cost at the mine in Greenland, royalty to Danish Government, ocean freight, inland or domestic freight, cost of separating the pure cryolite, grinding and packing in barrels, and other minor expenses.

According to a report furnished by the Danish Government the total production in Greenland was 8,874 metric tons in 1899, and 8,960 metric tons in 1900.

### IV. ALUMINUM.

The production of aluminum in the United States continues to be supplied by the sole producer, the Pittsburg Reduction Co., of Niagara Falls, N. Y., and during 1901 the quantity produced was practically the same as in the previous year, being 7,150,000 lb. The demand for the light metal in the electrical trade, particularly for purposes of conduction, and in the metal trade as a substitute for zinc and brass continues to be large. The subjoined tables give the production, imports and exports of aluminum in the United States and other of the principal countries in the world.

## PRODUCTION, IMPORTS, AND CONSUMPTION OF ALUMINUM IN THE UNITED STATES.

| Year.     | Production. |             |         | Imports. | Exports.  | Consumption. (b) |
|-----------|-------------|-------------|---------|----------|-----------|------------------|
|           | Pounds.     | Value.      | Per Lb. | Value.   | Value.    | Value.           |
| 1897..... | 4,000,000   | \$1,400,000 | \$0.35  | \$4,731  | (a)       | \$1,404,731      |
| 1898..... | 5,300,000   | 1,690,000   | 0.325   | 4,879    | \$239,997 | 1,454,898        |
| 1899..... | 6,500,000   | 2,112,500   | 0.325   | 14,840   | 291,515   | 1,596,895        |
| 1900..... | 7,150,000   | 2,288,000   | 0.32    | 47,698   | 261,881   | 2,053,847        |
| 1901..... | 7,150,000   | 2,238,000   | 0.31    | 104,168  | 183,579   | 2,158,589        |

(a) The exports from the United States were not reported by the Bureau of Statistics in this year. (b) The consumption each year includes a certain amount of manufactures imported; while the production represents the crude aluminum only. The bulk of the imports is in crude condition.

The statistics of aluminum production in Europe are not authoritative, several of the important companies being unwilling to make their figures public. The *Metallgesellschaft*, of Frankfort-on-Main, gives the following statistics for Europe in its last annual report, to which we have added our own figures for the United States, and those of C. Le Neve Foster for England previous to 1900.

## ALUMINUM: WORLD'S PRODUCTION AND COMMERCE. (IN KILOGRAMS.)

| Year.  | Germany.  | Switzerland. |          | England.    | France.     |          |          | United States. (a) |          | Total Production. |
|--------|-----------|--------------|----------|-------------|-------------|----------|----------|--------------------|----------|-------------------|
|        | Imports.  | Production.  | Exports. | Production. | Production. | Imports. | Exports. | Production.        | Imports. |                   |
| 1896.. | 591,500   | 700,000      | 661,100  | 130,000     | 370,000     | 7,012    | 192,769  | 599,676            | 316      | 1,789,676         |
| 1897.. | 942,400   | 800,000      | 706,000  | 6810,000    | 470,000     | 6,360    | 224,000  | 1,814,288          | 854      | 2,294,442         |
| 1898.. | 1,104,000 | 800,000      | 677,300  | 310,000     | 555,000     | 5,972    | 187,065  | 2,358,705          | 27       | 4,032,705         |
| 1899.. | 922,000   | 1,300,000    | 604,200  | 559,000     | 1,000,000   | 8,468    | 256,242  | 2,948,381          | 24,233   | 6,207,361         |
| 1900.. | 943,400   | 2,500,000    | 571,200  | 500,000     | 1,500,000   | 8,000    | 324,000  | 3,243,219          | 210,533  | 7,743,219         |

(a) The United States has been an exporter of aluminum for several years, but these exportations were not enumerated by the Bureau of Statistics of the Treasury Department until 1898, in which year they amounted to \$239,997. (b) C. Le Neve Foster, British Mineral Statistics for 1897.

*Prices.*—The quotations for aluminum ingots per pound at the close of 1901 were as follows: 99.75% Al, 33@37c.; 90 to 99% (impurities Fe and Si) 31@34c.; nickel-aluminum metal (aluminum with less than 10% Ni) 33@39c.; special casting alloy (containing over 80% Al), 27@35c. The import duty on aluminum in the United States is 8c. per pound on ingot and 13c. per pound on sheet and manufactured.

## PROGRESS IN THE ALUMINUM INDUSTRY IN 1901.

BY JOHN B. C. KERSHAW.

*Production.*—The number of works for production of aluminum has been increased from 8 to 9—during 1901—by the completion of the new factory at Shawinigan Falls in Canada, for the Pittsburg Reduction Co. It is unlikely that this factory will increase the American output of the metal seriously, before the end of 1902. Owing to the falling off in the demand for calcium carbide during 1901, the Schweizerische Gesellschaft f. Elektro-chemische Industrie of Basel, has decided to take up the manufacture of aluminum.

The figures for the actual amount of aluminum produced in 1900 and 1901, by the American and European factories, are again based on estimates—and not on official returns. The Neuhausen, and other European companies still

refuse to furnish figures for their output in 1900 and 1901, and as pointed out in *THE MINERAL INDUSTRY*, Vol. IX., p. 20, estimates based on the power available in the European works are wholly misleading.

TABLE I.—DETAILS OF ALUMINUM WORKS IN EUROPE AND AMERICA.

| No. | Name of Company.                                     | Locality of Works.    | Horse Power. |             | Process.          | Capital.    |
|-----|------------------------------------------------------|-----------------------|--------------|-------------|-------------------|-------------|
|     |                                                      |                       | Available    | In Use. (a) |                   |             |
| 1   | The Pittsburg Reduction Co.....                      | Niagara Falls.....    |              | 10,000      | Hall.....         |             |
| 2   | The Pittsburg Reduction Co.....                      | Niagara Falls.....    |              | (?)         | Hall.....         |             |
| 3   | The Pittsburg Reduction Co.....                      | Shawinigan Falls..... | 6,000        |             | Hall.....         |             |
| 4   | The British Aluminium Co.....                        | Foyers.....           | 14,000       | 5,000       | Heroult.....      | \$3,200,000 |
| 5   | Société Electro-Metallurgique Française.....         | Le Praz.....          | 12,500       | 5,000       | Heroult.....      | 2,880,000   |
| 6   | Compagnie des Produits Chimiques d'Alais.....        | St. Michel.....       | 6,000        | 2,000       | Hall & Minet..... |             |
| 7   | Société Anonyme pour l'Industrie de l'Aluminium..... | Neuhausen.....        | 4,000        | 4,000       | Heroult.....      |             |
| 8   | Société Anonyme pour l'Industrie de l'Aluminium..... | Rheinfelden.....      | 5,000        | 5,000       | Heroult.....      | \$3,077,000 |
| 9   | Société Anonyme pour l'Industrie de l'Aluminium..... | Lend Gastein.....     | 5,000        | (?)         | Heroult.....      |             |

(a) With the exception of the American and Canadian works, all these works manufacture other products in addition to aluminum.

The figures given in Table I. show that 26,000 H.P. is actually developed in these six factories, and assuming that only 0.617 kg. aluminum is produced per H.P. day, the capacity of these European works is over 5,200 tons per year. The highest estimate of their 1900 and 1901 production is however 4,600 tons and it is by no means certain that even this figure has been attained. The production at Foyers is however stated to be growing, and it is now three or four times greater than in 1896 and 1897. An estimate by a fairly reliable authority of the Neuhausen Co.'s production in recent years gives 1,000 tons in 1898, 1,500 tons in 1899 and 2,500 tons in 1900. Of the latter total, 1,000 tons is estimated to have been produced at Neuhausen, and the balance at Rheinfelden and Lend Gastein. The total European production in 1900 is estimated at 4,000 tons. The Metallgesellschaft of Frankfort published the following figures for aluminum production in 1900: Neuhausen, Rheinfelden and Lend Gastein, 2,540 tons; Foyers, 510 tons; St. Michel and Le Praz, 1,530 tons; Niagara Falls, 3,230 tons. *Total*, 7,810 tons (metric tons of 2,204 lb.). The actual 1900 production of aluminum was therefore probably between 7,000 and 7,500 tons, and the 1901 figures, if they could be obtained, would probably show a slight advance upon those for the preceding year.

The new plant of the Pittsburg Reduction Co. at Shawinigan Falls consists of two 3,000-H.P. turbines, each direct coupled to two 1,000-K.W. generators, giving a total available power of 6,000 H.P. The supply canal is 1,000 ft. long, by 100 ft. wide, and 20 ft. deep. It ends in a fore-bay 125 ft. above the two power-houses, to which the water is carried by three pen-stocks each 9 ft. in diameter. The main power-house of the Shawinigan Water & Power Co. contains two 6,000-H.P. turbines. The second power-house is smaller, and contains only the Pittsburg Reduction Co.'s generating units, whose works are 175 ft. above the power generating station. Aluminum conductors are used to convey the power. In order to protect the bare aluminum cables from the effects of exposure, a covered passageway has been built over the cables for the whole of the distance (about 400 ft.). This is the first practical recognition in America, that aluminum as a conductor does not resist exposure as well as copper; and

this erection of a covered way for the aluminum cables, is highly significant in its bearings upon the future of the metal as an electrical conductor. The works at Shawinigan Falls are stated to have cost \$250,000 and this locality has been selected for the site of the new factory, on account of the adjacent deposits of corundum.

As regards finance, the Aluminium Industrie Aktien Gesellschaft, of Neuhausen, still remains the most successful of the companies whose accounts are available for comparison. The gross profits in 1900, amounted to \$406,200 and this company has paid 12·5% for 1900, as compared with 13% for 1899. The valuation of their works is as follows: Neuhausen, \$960,000; Rheinfelden, \$1,140,000; Lend Gasten, \$720,000. All the patents owned by this company have been written off in the accounts and the reserve fund now stands at \$67,000. The total capital is \$3,077,000.

The British Aluminium Co.'s report for 1900, is far less satisfactory reading for the shareholders, but as all the ordinary shares in this company are stated to be held privately, the loss to the outside public is less serious than it might have been. Owing to an error in the 1899 stock taking, to excessive capital outlay on the carbide works and to the increased cost of fuel and other raw materials in 1900, the company finds itself with \$17,200 less profit than in 1899. The amount standing to the credit of the profit and loss account is therefore carried forward, and the preference shareholders have to go without the 7% dividend.

With regard to variations in cost and sale price of aluminum during 1901, there is little to report. The representatives of the leading European companies, and of the Pittsburg Reduction Co., have however recently held a meeting, in order to arrange for the future regulation of output and price. This can only mean an advance in price, and it is therefore probable that aluminum has touched bottom as regards cost to the consumer, until a cheaper raw material than refined alumina is used for the reduction process.

The following are the November, 1901, American prices for aluminum: 99% Al and over, 33 to 37c. per lb.; 90 to 99% Al (impurities, Fe and Si), 31 to 34c. per lb.; drawn rod, and wire, .0000 to No. 6, B. & S. Gauge, 39·5c. per lb. There is a deduction of 7c. off the list prices, for rod and wire, with 20,000-lb. orders; and aluminum for transmission lines, therefore, costs 32·5c. per lb. in America. The import duty on aluminum in the United States is 8c. per lb. on ingot metal, and 13c. per lb. on sheet and manufactured metal; so the Pittsburg Reduction Co. and its customers are well protected from European competition.

The November price list of the Foyers company gives the following figures:

|                  |                                 |                    |
|------------------|---------------------------------|--------------------|
| Ingot metal..... | { Bars 98-99% Al.....           | 27·8 cents per lb. |
|                  | { Special for steel makers..... | 27·8 cents per lb. |
|                  | { Special alloy.....            | 27·8 cents per lb. |
|                  | { Wolframium alloy.....         | 33·0 cents per lb. |
|                  | { Rumanium alloy.....           | 33·0 cents per lb. |

Three cents extra per lb. is charged on the above ingot metal for a guarantee of over 99% Al.

The average sale price of the Pittsburgh Reduction Co.'s production, worked out to 32·7c. per lb. in 1899, and to 32·3c. per lb. in 1900.

No very noteworthy figures relating to the efficiency of the process by which aluminum is produced, have been published during 1901. An anonymous writer in a London journal<sup>1</sup> has stated that at Foyers 12 E.H.P. hours were now yielding 1 lb. aluminum. This is equivalent to 0·909 kg. per E.H.P. day, or 0·76 kg. per H.P. day; and is an advance upon the earlier published figure, of 0·617 kg. aluminum per E.H.P. day.

With regard to patent litigation, the year 1900 has witnessed two decisions of importance. The application made by the British Aluminium Co. to the English courts, praying that an extension of time for the Heroult patent might be granted, failed, and the patents owned by this firm therefore lapse in 1902. In America the long drawn-out litigation between the Electric Smelting & Refining Co. of Cleveland, and the Pittsburgh Reduction Co., has been settled by a judgment in favor of the latter company. This action was commenced in 1897, and was based upon an alleged infringement of the Bradley patents issued in 1892, and owned by the Cleveland company. The most important event of the year is the granting of patents to Hall, of the Pittsburgh Reduction Co., for improvements in the method of preparing bauxite for the reduction process. At present the cost of the refined alumina is one of the chief items in the total cost of manufacturing aluminum and no great reduction in the cost of the metal can be expected until this heavy item of expenditure is lessened. Hall proposes to prepare bauxite for the reduction process by submitting it to a preliminary heating in an electric furnace for some hours, in presence of carbon and aluminum. The ferric oxide and silica are reduced to the metallic state and form a heavy alloy with the aluminum, which when cooled can easily be detached from the mass. The new Hall procedure may be widely adopted if the cost of treatment is not too high. Blackmore has patented during 1901 a method of reducing alumina by means of calcium carbide; the alumina being used as raw material in a bath of fused cryolite and lithium chloride. The cost of working this process is stated to be only 7c. per lb., but until further particulars are published, this statement must be accepted *cum grano salis*. Moody and Tucker have also been conducting researches upon the action of calcium carbide on alumina, and they find that if calcium carbide be present, the oxide can be reduced to aluminum by carbon in presence of the electric arc. Such reduction does not occur when calcium carbide is absent.<sup>2</sup>

**UTILIZATION.—Electrical Conductors.**—The use of aluminum as a substitute for copper for bare overhead transmission lines has attracted much attention throughout 1901, and in America especially, this outlet for the metal is becoming of marked importance. The difficulty with regard to the low and variable tensile strength of pure aluminum has been overcome by the use of stranded cables. The addition of small amounts of copper or iron in order to increase the strength of the metal is now recognized as a mistake, since it seriously reduces the conductivity and renders the line less resistant to weather influences.

<sup>1</sup> *The Engineer*, March 22, 1901.

<sup>2</sup> *Journal of the Society of Chemical Industry*, October, 1901.

In Europe progress in the use of aluminum as an electrical conductor is less rapid and Italy is the only country which yet possesses overhead bare aluminum transmission lines, working in connection with a central power generating station. The Neuhausen and the Foyers companies both use aluminum as a conductor within their own works, but these are private installations and are not worked upon a commercial basis. At the Glasgow Exhibition in 1901, aluminum was employed for the outdoor lighting and 10,000 yd. of bare wire are said to have been used for the arc-lamps which were run on 500-volt circuits. Here again the trial was not a commercial one, for the British Aluminium Co. loaned the wire required for this work, to the Exhibition authorities.

The Niagara Falls Power Co. has used the new metal for the second three-phase transmission line, 22 miles in length, between Niagara Falls and Buffalo. Three cables have been erected, each consisting of 37 strands. The resistance of each cable is .032 ohm at 0°C., the sectional area is 500,000 cm. and the tensile strength is 25,000 lb. per sq. in. The estimated loss of power when transmitting 10,000 H.P. at 22,000-volts pressure, is 7%. The original copper cable contained 19 strands. The spans have been increased from 75 to 112 ft., and the pressure on both lines, which run for many miles parallel, has been raised to 22,000 volts. By this means the capacity of the two lines has been raised to 30,000 H.P. and it is hoped that shortly all of this power will be disposed of in Buffalo, and its neighborhood.

Hoopes<sup>a</sup> has stated that aluminum collects less snow in bad weather than copper. This observation, if correct, may be an effect due to the different specific heats of the two metals, as these stand in the ratio 100:47, that of aluminum being the higher. Hoopes recognizes that first cost is only one factor of the problem relating to the use of aluminum in place of copper for conductors, and he states that reliability, durability, and cost of erection are other factors of almost equal importance. With regard to the first, he states that the early breaks in America with aluminum were due to the use of alloys, and that none have occurred since the pure metal was used. As regards durability, he states that aluminum is only attacked chemically by HCl, Cl, and NaOH, and that in these cases a protective coating of  $Al_2O_3$  will be formed. In his opinion, the cost of erecting aluminum wires should not exceed that of copper, because it is lighter, and longer spans with fewer poles can therefore be used. The experience gained in my own experiments, will not allow me to support all of these opinions. Hoopes also states that pure aluminum is now alone used in the United States for wire drawing, it having been apparently recognized that the alloys of aluminum with iron or copper are not so durable as aluminum alone, although the tensile strength of these alloys is greater.

The Italian transmission line mentioned above, extends between Sarno, Pompeii, and Forre Annunziante. The total power transmitted is only 450 H.P. and the voltage is low, being 3,600. Three aluminum conductors are in use, 1.8, 9.0 and 2.0 miles in length, respectively.

An important but anonymous report upon the bare overhead aluminum lines

---

<sup>a</sup> *The Street Railway Review*, Jan. 15, 1901.

erected in 1899 for the electric lighting of Northallerton, England, appeared in March, 1901.<sup>4</sup> For this installation, wire testing 98.1% Al with a conductivity of only 51 (copper, 100), is stated to have been used. The joints were made by means of screwed sockets of brass. These held well, but they gradually failed owing to the formation of oxide. The copper and aluminum joints, made by twisting the two wires together, lasted only six months. The extra cost of erecting and maintaining the aluminum network of wires, as compared with copper, is stated to have more than balanced the saving in first cost.

Some of the statements in this report have been disputed by the representatives of the British Aluminium Co. and repeat orders for aluminum wire are said to have been given by the Northallerton Electric Light & Power Co.

A minor use of aluminum for conducting purposes is reported in connection with the equipment of the new electro-chemical laboratory at Victoria University, Manchester, England. In this case aluminum has been used for some of the leads, and the joints have been made with an ordinary blowpipe, by a method which appears to be similar to that patented by Heraeus, details of which are given in *THE MINERAL INDUSTRY*, Vol. IX., p. 29.

A new transmission line of aluminum is being erected by the Snoqualmie Falls Power Co. in California. The new line will extend from the power station at the Falls to Seattle and Tacoma, distant 32 and 44 miles respectively. The new line will require 125 tons of the metal and it is intended to transmit 12,000 H.P. at 30,000-volts pressure.

With regard to the aluminum wires erected in Chicago in November, 1899, in connection with the telephone fire-alarm system, the city electrician reports, that these are answering well and that no special troubles have yet been experienced with them.

During the discussion upon my paper before the London Institution of Electrical Engineers in January, 1901,<sup>5</sup> Mr. J. Gavey gave some interesting details relating to the trials of aluminum by the post-office authorities in Staffordshire, England. In December, 1900, between 18 and 20 miles of aluminum wire were in use, 15 miles of which were erected in the "Potteries." Within 14 days of the erection of this wire, a heavy gale was experienced, resulting in eight or ten breaks in the spans. These breaks were attributed to variations in the mechanical or chemical constitution of the wire. Similar breaks were experienced at first with the aluminum wire used for telephone purposes in California by the Pacific Telephone & Telegraph Co. The weight of the wire used in Staffordshire was 78 lb. per mile; the diameter was 1.24 mm., the tensile strength was 12.56 tons per sq. in. and the specific resistance was 2.974 ohms.

In a recent letter, Mr. J. Gavey, the English post-office electrician, informs me that the post-office authorities have been investigating the cause of the failure of the aluminum telegraph lines erected in December, 1900. The experiments show that the limit of elasticity of aluminum under constant stress is much diminished. A wire breaking under the ordinary conditions of trial at 325 lb.,

---

<sup>4</sup> *Electrical Review* (London), March 8, 1901.

<sup>5</sup> *THE MINERAL INDUSTRY*, Vol. IX., p. 31, and the *Journal of the Proceedings of the Institution of Electrical Engineers*, Vol. XXX., 1901.

with a maximum extension of 0·5 in., when submitted to a constant stress of 220 lb. broke at the end of 525 hours, the permanent extension being 2·54 in. The results given above are highly important in their bearing upon the use of aluminum for overhead conductors.

In the same discussion Prof. Forbes stated that two lengths of aluminum wire, drawn from Foyers and Neuhausen metal respectively, had been exposed at Fettercairn, Scotland, for 18 months and 3 years, and that in December, 1900, both wires were in good condition. Mr. Ristori made a similar report regarding the aluminum conductors in use at Foyers.

As regards the total weight of aluminum used in 1900 and 1901, for conducting purposes, no reliable figures can be given. As already stated, the largest use of aluminum for this purpose is in America, and Hoopes states that two recent orders placed in that country have amounted together to 1,250,000 lb. It is therefore evident that half a dozen such orders would absorb a very large portion of the annual output of the Niagara works. The break in the price of copper, which has occurred during 1901, will however affect the sale of aluminum for conducting purposes; since with copper again at £50@£55 per ton, there will be little inducement to use the lighter metal, until a further reduction in its cost has been brought about. As pointed out on page 23, this reduction in the cost of aluminum is now within sight. The price at which ingot aluminum must be sold to equal electrolytic copper at £55 per ton, can be calculated by aid of the following formula, in which P.p. represent the price, C.c. the conductivity, and S.s. the specific gravity, of copper and aluminum respectively:—

$$S \times P \times c = s \times p \times C.$$

Taking the following values:  $S = 8\cdot93$ ,  $C = 100$ ,  $P = \text{£}55$  per ton;  $s = 2\cdot68$ ,  $c = 59$ ,  $p = x$ , and substituting these in the equation already given we obtain:  $8\cdot93 \times 55 \times 59 = 2\cdot68 \times x \times 100$ , and  $x = 8\cdot93 \times 55 \times 59 \div 2\cdot68 \times 100 = \text{£}109\cdot40$  per ton or 23·4c. per lb.

Whether aluminum will ever be sold of the requisite degree of purity at this price, remains to be seen.

*Balloons and Boats.*—The interest in aluminum as the lightest known metal has been transferred by the exploits of M. Santos Dumont from the sea to the air, and the metal or its alloys is being used by builders for the construction of the framework of the majority of the navigable balloons now being experimented with. Count Zeppelin's air-ship, in the construction of which aluminum was used, has not indeed been heard of during 1901, but other vessels of similar design have been much to the front. M. Santos Dumont, the Brazilian who circumnavigated the Eifel Tower and won the Deutsch prize, is believed to have used aluminum alloys largely in the construction of his air-ship. M. Roze, of Paris, also is said to be employing 15,000 ft. aluminum rod and tubing, for the framework of his new navigable balloon. This vessel when completed will possess two cigar-shaped balloons enclosed in an aluminum framework, each frame being 140 ft. long and 22 ft. in diameter.

With regard to the use of aluminum for boat building, this metal was used for

the deck plates of the English racing yacht Shamrock II. Some difficulty was experienced by the builders at first in handling these plates, due to lack of knowledge of the properties of aluminum.<sup>6</sup> The aluminum deck was covered with thin wood, to act as a protection and to afford the requisite foothold. The American racing yacht Independence also was built with deck plates of an alloy of aluminum, of a tensile strength of 35,000 lb. per sq. in. These plates were covered with canvas put on with marine glue, in order that they might be protected from the action of the salt water. The ultimate goal of these plates and of those of Shamrock II. is probably the scrap heap; for it was reported that the New York scrap aluminum market had been disorganized in October, by the sale of the deck plates of the old cup-yacht Defender. These plates were so badly corroded that the metal remaining was of little value. It is indeed now generally recognized that aluminum will not stand the action of salt water for any length of time, even when covered with a protective coating.

*Cycles and Motor-cars.*—The use of aluminum alloys in motor-car construction is extending; and according to Richards,<sup>7</sup> Corbin of Paris is turning out 7 tons of aluminum castings per week, chiefly for automobile builders. Care is necessary in cleaning and preserving these portions of the framework of the vehicles, and the use of oil is recommended to protect the alloys employed, from the effects of moisture or mud. This would seem to indicate that automobilists have wisely recognized that aluminum alloys, though light, are not resistant to all weather conditions, and the disappointment if corrosion should occur will be less fatal than in the case of the boat-building industry, in which expectations of the value of the new metal were unduly raised.

*Printing.*—The substitution of aluminum for stone in lithographic work is believed to be increasing and some interesting letters<sup>8</sup> have been published from lithographic firms using aluminum in their printing machines. The chief advantages over stone were stated to be economy in first cost, and greater speed in obtaining impressions. It is admitted that experience is required, before good results can be obtained with aluminum and here, as in the use of the metal for other purposes, it is unwise of those interested in the sale of aluminum to press unduly its superior advantages. Practical hints upon the precautions to be observed in using aluminum for lithographic work will be found in the publication named below.<sup>9</sup>

*Foundry and Metallurgical Uses.*—The use of aluminum in foundry and casting work is one of the most important outlets for the metal. According to Heroult, 2,500 tons of the lower grades of aluminum are now used per annum in the steel industry alone. The affinity of aluminum for oxygen, which renders it of value in steel casting, is also the basis of its use for producing heat by the Goldschmidt process. The Chemische-Thermo Industrie, formed to exploit this process, now places on the market the mixture of aluminum powder and ferric oxide under the trade name of "Thermit." The mechanical details of the application of the method to rail-welding and to repairs of propellor shafts have been much improved during 1901. The temperature attained by

<sup>6</sup> *The Aluminum World*, May, 1901.

<sup>7</sup> *Journal of the Franklin Institute*, February, 1901.

<sup>8</sup> *The Aluminum World*, January, 1901.

<sup>9</sup> *Ibid.*, January to December, 1901.

the molten iron, when this process is worked under the most favorable conditions, is said to approach  $3,000^{\circ}\text{C.}$ , and it is evident that at such a temperature, welding work can be carried out, which would be most difficult or impossible to perform, by any other means, as for example, the repairing of propellor shafts in mid-ocean. The application of the method to the reduction of refractory oxides does not appear to have advanced beyond the laboratory stage excepting in the case of chromium and its alloys, which are now produced by the Goldschmidt Co., at Essen. The method however is applicable to the reduction of practically all of the heavy metallic oxides, and any of these metals can now be prepared at a moderate cost from its corresponding oxide. When using an excess of aluminum, alloys of aluminum and the concerned metal are obtained. In this way Guillet has recently prepared alloys of aluminum and tungsten.<sup>10</sup> Vanadic oxide has also been reduced with success by the Goldschmidt process. The details of the method and its application in this particular instance, have been described by Smith.<sup>11</sup> Vanadium added to steel increases its tensile strength, and Smith gives tests showing a gain of 10 tons per sq. in., as the result of an addition of 0.56% V to tool steel.

*Miscellaneous Uses.*—An aluminum alloy capable of taking a high polish is now being used for constructing the bright parts of oil stoves, and in France and in Italy a large and growing industry in the new metal is being built up by the manufacturers of funeral wreaths. During 1901 a proposal has been made to use thin aluminum foil in place of paper for printing and other purposes, but the cost would be prohibitive. The use of aluminum for large castings is extending. An English firm which has made a special feature of this work, recently cast a motor-engine cylinder and bed-plate, weighing 300 lb. If cast in iron, this would have weighed 800 lb.; the saving in weight was therefore considerable. At the Buffalo Exposition, 1901, the Pittsburg Reduction Co. exhibited an octagonal house, 22 ft. in height, and covering 15 sq. ft., built completely of No. 24 sheet aluminum.

The use of aluminum for the manufacture of novelties is a special branch of the business which has been energetically pushed in the United States. Small articles of aluminum, such as trays, paper cutters, calendars, mirrors, boxes, etc., stamped with the name of the advertising firm, find ready acceptance at the hands of customers, and so long as the metal retains its brightness, they form most useful advertisements. This use for the metal might be developed more vigorously in Europe where novelties in aluminum are the exception rather than the rule.

*Alloys of Aluminum.*—Two new alloys have appeared during the year and are known as nickel-aluminum and "minckin." The former consists mainly of aluminum with nickel and copper, the alloy having a sp. gr. of 2.86. The difficulty of alloying aluminum of low melting point with nickel of high melting point is surmounted by alloying the aluminum first with copper, which prepares it to take up the nickel later. Tests have shown a tensile strength for nickel-aluminum of 16.44 tons per sq. in. Minckin is an alloy similar to the so-called "new silver" but con-

<sup>10</sup> *Comptes Rendus*, May 6, 1901.

<sup>11</sup> *Journal of the Society of Chemical Industry*, December, 1901.

tains more nickel. Ordinary "new silver" contains 26% Ni, an amount beyond which it was formerly difficult to go, owing to the development of gases in the mass. Minckin is being largely used on account of its resistance to the corrosive action of weak acids and alkalies.

Partinum, the alloy of aluminum and tungsten, is being manufactured in Paris and the employment of this alloy, which is said to possess a tensile strength of 49,000 lb. per sq. in., is believed to be growing. The laboratory production of alloys of aluminum and tungsten by the Goldschmidt method, has already been referred to.

Albradium, an alloy of copper, nickel, zinc, phosphorus, and aluminum, is manufactured by a company in London, and samples of this alloy were shown at the Paris (1900) Exposition. Magnalium, the alloy of aluminum and magnesium, is manufactured by the Deutsche Magnalium Gesellschaft and is protected by German Patent No. 113,935 of 1899. The alloys containing from 2 to 10% Mg are found to be the most valuable, and their ductility and malleability can be much increased by rolling and annealing. The resistance offered by this alloy to the effect of salt water or to "weathering" is low, and it cannot therefore be employed for marine work, or for outdoor decorative work in bad climates.

Jos. W. Richards has published some information concerning the alloys of aluminum and zinc.<sup>12</sup> The hardest and strongest of the aluminum and zinc alloys is that containing two parts of aluminum to one of zinc, while the alloy with three of aluminum to one of zinc is the most generally useful and has special application for making scale beams, surveying and astronomical instruments, gear wheels, etc. With decreased percentage of zinc, the hardness and the tensile strength of the alloy are decreased, thus affording material for special application where the previously mentioned alloys are too hard. Alloys containing less aluminum than zinc, do not appear to have any specially valuable mechanical properties.

Tetmayer has published researches bearing on aluminum bronzes.<sup>13</sup> The tests were carried out in the Laboratory of the Zurich Polytechnic at the request of the Neuhausen Aluminium Co. Three series of experiments were planned, but only those relating to aluminum bronzes were completed. The specific gravity of the bronzes first rises and then falls as the percentage of aluminum increases. The maximum strength for soft alloys was obtained with 3.4% Al, and for hard alloys with only 1.4% Al. Aluminum bronze containing 10% Al with 1.5% Fe and Si, is too brittle to be of any practical value. As regards the use of aluminum bronze for bearings, the hard variety with less than 89.60% Cu stood the tests well, while the soft bronzes with less than 6% Al, heated and lost rapidly in weight.

In a contribution to the French Academie des Sciences<sup>14</sup> M. Le Bon has described experiments upon the effect of minute quantities of mercury on aluminum. Such an alloy was attacked by water and by all acids, with progressive and complete oxidation of the aluminum. These results show the necessity for great care in the manufacture of aluminum, for minute traces of metals other

<sup>12</sup> *The Aluminum World*, May, 1901.

<sup>13</sup> *Revue de l'Electricite* (Berne), Aug. 31, 1901.

<sup>14</sup> *Comptes Rendus*, January, 1901.

than mercury, may have equally disastrous results upon the durability of the metal when exposed to water or damp air.

*Soldering and Welding.*—Patent solders still continue to be manufactured and sold, although, on account of the remarkably high affinity of aluminum for oxygen, no metal can be used with it for jointing purposes that will not form the electro-negative element of an electric couple, when the joint is immersed in water or is exposed to a damp atmosphere. For this reason, all soldered joints under these conditions are certain in time to become weak and to show disintegration. The only two satisfactory methods of jointing aluminum are therefore the mechanical, and the method devised by Heraeus. The former has been used for most of the American transmission lines, the Mac-Intyre sleeve joint being that usually employed. The latter, known as the autogenous weld, can be easily learned and applied.

In the discussion upon the paper by Morrison referred to below, Bubb stated that the method of jointing aluminum wires by the autogenous method, could be easily mastered, and that any man with a blowpipe could make satisfactory joints after 30 minutes' practice.

Gavey gave some interesting details relative to the jointing of aluminum wires, in the discussion already referred to.<sup>15</sup> He stated that the question of soldering seemed to be solved so far as the mere soldering of joints was concerned, but unfortunately the heat necessary for the soldering annealed the wire and reduced its strength exactly one-half. Ultimately the wires were run out in the full length of the coil, each coil being erected on an insulator, and the joint soldered in a little loop, so that the annealing of the wire itself had no injurious effect on the strength of the portion that was suspended.

The method described above, for overcoming the difficulty caused by the loss in tensile strength due to the heating of the wire when jointing, in conjunction with the autogenous weld, will probably be generally adopted for overhead wires in the future.

*Plating.*—Further details of the Wachwitz method of plating aluminum have been published during 1901. This method depends upon rolling plates of aluminum and copper together while heated and is therefore a mechanical process. In the first rolling, the aluminum is used as a very thin foil, and in the second rolling a thicker plate of aluminum is used with the copper. The method is said to yield good results and the finished copper-aluminum sheets can be used for various industrial purposes. Nothing further has been published concerning the exhibit of an electro-deposited plate of aluminum at the Paris (1900) Exposition, or the method by which it was produced. An interesting method of purifying crude aluminum, by using it as a molten anode in a bath of fused fluorides, with molten aluminum as cathode, has been patented by Hoopes.<sup>16</sup> This process can however never occupy the place in the aluminum industry that electrolytic refining has taken in the copper industry, for silicon and iron, the impurities of commercial aluminum, are practically valueless, and can never pay for their recovery in an electrolytic bath. The Hoopes patent has been

<sup>15</sup> *Proceedings of the Institution of Electrical Engineers*, Vol. XXX., Part 149.

<sup>16</sup> United States Patent No. 673,364. 1901.

assigned to the Pittsburg Reduction Co. As regards the difficulties met with in plating upon aluminum, Ryan<sup>17</sup> recommends a preliminary treatment with phosphoric acid before immersion in the plating bath. The selection of aluminum plates of uniform composition is also held to be a necessity for the attainment of good results, since silicon and iron are often accumulated in spots, and these give rise to local circuits in the electroplating bath.<sup>18</sup>

*Properties.*—The properties of aluminum in certain of its commercial forms have already been discussed elsewhere in this section under the headings of *Alloys* and *Electrical Conductors*. As regards electrical conductivity, Hoopes states that pure aluminum only is now used for transmission cables, and that at 70°F. the relative conductivity of aluminum and copper may be taken as 62.9:100. The following tests, recently given to the public, were made by the officials of the Pittsburg Reduction Co. in 1898, and are interesting as showing the marked effect of small amounts of impurity upon the conductivity of unannealed aluminum:—

| Composition. | Resistivity. | Composition. | Resistivity. |
|--------------|--------------|--------------|--------------|
| 99.66% Al    | 2.45         | 97.16% Al    | 2.88         |
| 99.58% Al    | 2.58         | 94.89% Al    | 3.01         |
| 98.77% Al    | 2.84         |              |              |

The conductivity is of course the reciprocal of these figures, but in the absence of details as to the size of the wire used in carrying out the tests, it cannot be expressed in the usual way, namely, as percentages of the conductivity of electrolytic copper of equal sectional area and length.

With reference to the resistance offered by aluminum and its alloys to weather influences, the exposure tests that I commenced at St. Helens and Waterloo in 1899, are still being continued, and the further results of these will be published in the course of 1902. Details of the figures obtained during the first 10 months' exposure were given in *THE MINERAL INDUSTRY*, Vol. IX., p. 31. The contributions of Prof. G. Forbes and Mr. E. Ristori to the discussion which followed the reading of my paper in January, 1901, have already been referred to under *Electrical Conductors*. As regards the composition of commercial aluminum now being placed upon the market as first grade metal, the following figures have been published for the product of the British Aluminium Co.: Al, 99.58%; Si, 0.18%; Fe, 0.24%. This compares favorably with the Pittsburg Reduction Co.'s 99.66% metal.

Prof. Wilson, in a paper read before the London Institution of Electrical Engineers in December, 1901, gave a large number of chemical and physical tests of aluminum and its alloys, a portion of which is reprinted on page 32.

It will be noticed in the above table, that the conductivities range from 48.6% to 61.5%; the latter being obtained with commercially pure aluminum containing 0.14% Si and 0.31% Fe. The breaking strain of this wire was 28,200 lb.; while the strongest alloy was that containing 1.08% Cu (No. 22 in the Table) the breaking strain in this case being 45,900 lb.

Morrison, in his paper read before the same Society at Glasgow, dealt with the

<sup>17</sup> German Patent No. 116,819, 1899.

<sup>18</sup> *Electrical Review* (New York), May 18, 1901.

manufacture of aluminum at Foyers and with the well-known uses of the metal, but added little information to what has already been published in this and previous volumes of THE MINERAL INDUSTRY. With reference to the use of aluminum as an electrical conductor, he stated that the wires at Foyers after four years' use, showed no appreciable deterioration.

## V. ALUM AND ALUMINUM SULPHATE.

ALUM, ARTIFICIAL.—The production of alum and aluminum sulphate in the United States during 1901 increased very largely, the reported output of aluminum sulphate amounting to 74,721 short tons, as compared with 61,678 short tons in 1900, while that of crystallized alum was 7,755 short tons, as compared with 20,531 short tons in 1900. The apparent large decrease in the production of crystallized alum results from the method of calculation necessary previous to 1901, the year in which statistics of production were first collected directly from the producers.

The statistics of the production of alum and aluminum sulphate given in the above table previous to 1901 are computed from the consumption of bauxite and cryolite in the United States, and the production of aluminum, it being assumed that what is not used for aluminum is used for making the sulphates. The yield of both American and imported bauxite is well known, and consequently

## UNITED STATES PRODUCTION AND IMPORTS OF ALUM.

| Year.  | Production.    |           |             |                    |             |             |                                            | Imports. (a)    |                |          |             |

| 1901.. | 7,775          | 233,250   | 30.00       | 74,721             | 1,793,304   | 24.00       | .....                                      | 2,026,554       | (b) 1,091      | 20,761   | 19.05       |

(a) Includes alumina, alum, alum cake, aluminum sulphate, aluminous cake, and alum in crystals or ground.  
 (b) There was also imported in 1898, 1,205 short tons (\$76,884) of aluminum hydrate, or refined bauxite, in 1899, 1,926 short tons (\$119,202), in 1900, 2,307 short tons (\$148,532), and in 1901, 1,996 short tons (\$146,462).

this is an accurate method of determining the production in so far as it is expressed in terms of crystallized alum. The division into crystallized alum and aluminum sulphate is estimated, and consequently is only approximate. However, since it is apt to be misleading to report the entire production as crystallized alum, of which really only a comparatively small amount is made, the statistics for 1897 to 1900 have been reported in the modified form. Any apparent discrepancy is thus accounted for. The following companies produced one or both of these salts during 1901: The General Chemical Co., The Pennsylvania Salt Co., Harrison Brothers, Charles Lenig & Co., The Erie Chemical Co., The Cochrane Chemical Co., The Merrimac Chemical Co., and The Detroit Chemical Co. The production of alum shale in the United Kingdom in 1900 was 1,308 long tons (£164), as compared with 5,820 long tons (£728) in 1899.

**Market Conditions.**—New York prices of alum during 1901 were \$1.65@ \$1.75 per 100 lb. for lump, \$1.85 ground, and \$2.50@ \$3 powdered. Aluminum sulphate, owing to competition, was unsteady at \$1.15@ \$1.25 per 100 lb. for the commercial quality, and \$1.50@ \$2 for the purest quality.

**NATURAL ALUM.**—The Alum Co., at Bullahdelah, New South Wales, during 1900 shipped 1,915 long tons of alunite (£5,745) to the United Alkali Co.'s works at Runcorn, near Liverpool, England, as compared with 921 long tons (£2,763) in 1899.

## AMMONIA AND AMMONIUM SULPHATE.

THE production of ammonia (reported as its equivalent sulphate salt) and ammonium sulphate by by-product coke oven plants in the United States during 1901 is estimated at 66,000 short tons, and for 1900, at 63,800 short tons, which shows the active development of this industry due chiefly to the increase in the number of by-product coke ovens now in operation. The manufacture of ammonia and ammonium sulphate in the United States and in Europe during recent years is discussed in complete detail in the paper by Dr. F. Schniewind, on "The Manufacture of Coke, with Especial Reference to the Markets for By-products," which is given elsewhere in this volume.

The imports of ammonium sulphate into the United States for the past five years are given in the tables of imports and exports at the end of this volume.

According to the annual report of the Chief Inspector of Alkali Works, etc., for the United Kingdom, the production of ammonium sulphate during 1901 amounted to 220,000 long tons, as compared with 210,000 long tons in 1900. The details of production are given in the subjoined table:—

PRODUCTION OF AMMONIUM SULPHATE IN THE UNITED KINGDOM. (IN TONS OF 2,240 LB.)

|                  | 1898.   | 1899.   | 1900.   | 1901.   |                 | 1898.   | 1899.   | 1900.   | 1901. (a) |
|------------------|---------|---------|---------|---------|-----------------|---------|---------|---------|-----------|
| Gas works.....   | 129,500 | 136,529 | 138,000 | 148,500 | Coke works..... | 11,568  | 15,209  | 15,000  | 19,000    |
| Iron works.....  | 18,000  | 17,963  | 18,000  | 16,000  |                 |         |         |         |           |
| Shale works..... | 37,264  | 38,780  | 39,000  | 36,500  | Total.....      | 196,357 | 208,481 | 210,000 | 220,000   |

(a) Estimated. (b) Of this amount England furnished 134,000 tons, Scotland 73,000 tons, and Ireland 3,000 tons.

The world's production of ammonium sulphate during 1901 exceeded 523,000 metric tons, valued at \$26,673,000. Of this quantity, Germany contributed 130,000 tons and France 38,000 tons. The product is used mainly in the manufacture of fertilizers. In Germany there are 4,215 Otto-Hoffman coke ovens for the saving of by-products.

Average price per 100 lb. of gas liquor ammonium sulphate, basis 25%, in New York in 1899, 1900 and 1901, was as follows:—

| Year.     | Jan.    | Feb.    | Mar.    | April.  | May.    | June.   | July.   | Aug.    | Sept.   | Oct.    | Nov.    | Dec.    | Average. |
|-----------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|----------|
| 1899..... | \$2.716 | \$2.663 | \$2.667 | \$2.810 | \$2.975 | \$3.337 | \$3.190 | \$3.111 | \$3.065 | \$2.975 | \$2.850 | \$2.905 | \$3.088  |
| 1900..... | 2.925   | 2.956   | 3.081   | 2.981   | 2.887   | 2.840   | 2.725   | 2.825   | 2.755   | 2.750   | 2.773   | 2.775   | 2.856    |
| 1901..... | 2.788   | 2.801   | 2.813   | 2.700   | 2.731   | 2.750   | 2.721   | 2.745   | 2.769   | 2.819   | 2.820   | 2.794   | 2.771    |

## ANTIMONY.

THERE was no material change in the antimony industry in the United States during 1901 except the very large decrease in the imports of ore due to over-importation in 1900. The control of the production and trade continues to remain in the hands of Mathison & Co., of London, with works at Chelsea, Staten Island, N. Y., and of the affiliated concern, the Chapman Smelting Co., with works at San Francisco. Practically all of the domestic ore smelted is treated at the San Francisco works, which refines as well antimony regulus imported from Japan. The supply of antimony for domestic consumption as metal or as lead alloy is derived from the following sources: (1) hard lead produced as a by-product from the smelting or refining of lead ores and bullion of both domestic and foreign origin, (2) imported ores or crude antimony, (3) imported metal or regulus, and (4) domestic ores. The quantity produced from domestic ores during 1901 was 50 tons, which is an insignificant proportion of the total domestic consumption. The only ore of commercial value in the United States is the mineral stibnite ( $\text{Sb}_2\text{S}_3$ ) which was produced to the extent of a few hundred tons from mines in California, Idaho, and South Dakota. Many stibnite deposits occur in other Western States as well, but on account of the high cost of transportation to smelters they cannot be operated at a profit.

The details of imports, production, and consumption of antimony in the United States, from 1897 to 1901, inclusive, are given in the subjoined table. There was a small export of 25 tons antimony ore during 1901, valued at \$1,536.

### IMPORTS, PRODUCTION, AND CONSUMPTION OF ANTIMONY IN THE UNITED STATES.

| Year. | Imports.          |          |           |           |              | Production.       |                    |                         |                                 | Con-          |
|-------|-------------------|----------|-----------|-----------|--------------|-------------------|--------------------|-------------------------|---------------------------------|---------------|

| 1899  | 3,160,697         | 240,968  | 3,962,133 | 47,841    | 288,829      | 1,586             | 234                | 1,041                   | 1,495                           | 4,356         |
| 1900  | 3,632,843         | 285,749  | 6,035,734 | 78,581    | 364,330      | 2,476             | 151                | 1,599                   | 1,827                           | 6,063         |
| 1901  | 3,640,505         | 254,529  | 1,731,497 | 24,068    | 278,597      | 2,335             | 50                 | 364                     | 1,837                           | 4,486         |

(a) Estimated at 25% of the total quantity of hard lead produced. (b) Estimated at 40% extraction, from average of 52.5% antimony in ore.

The table given above shows the constantly increasing quantity of antimony obtained from foreign ores and regulus, which is due mainly to cheap ocean freight rates from foreign countries, where the ores are mined at a low cost.

(a) From the official reports of the respective countries. (b) Crude antimony and regulus. (c) Not reported. (d) Includes manganese. (e) Statistics not yet available.

*Algeria.*—The production of antimony in Algeria in 1900 amounted to 180 tons, valued at \$10,470. Of this 106 tons were shipped from the Taya mines to Marseilles, the freight rate being £11 4s. per ton, which corresponds to 3s. 10d. per unit. The extent of the mining concessions in this province is reported at 2,632 acres.

*Chile.*—The exports of antimony from Antofagasta in 1900 amounted to 302 long tons, valued at £22,569; there were also exported 877 long tons of antimony ore valued at £65,510.

*France.*—The principal center of the antimony industry in France is at Auvergne, Brioude (Haute-Loire). The smelting works are at Couches (Cantal), Blesle, and Biroude, and the ore supply is derived from the mines Licoulne-Bessade, Loubelhae, Ouche, and Couches. The ore is very low grade, averaging but 7 or 8% antimony, and is roasted in a special furnace to produce the volatile antimonious oxide, which is collected in a condensation chamber. The waste gases are used again, thus diminishing the loss. The product, consisting of Sb<sub>2</sub>O<sub>3</sub> with traces only of Sb<sub>2</sub>O<sub>4</sub> and Sb<sub>2</sub>O<sub>5</sub>, is used in part for the preparation of antimony compounds for dyeing purposes, which is exported, amounting in value to \$80,000 annually, and in part for the production of the so-called "star antimony" metal by heating the oxide in a crucible with coal and an alkaline slag. The metal gives an analysis of 99.94% Sb. The mines operated by the three smelting works produce annually from 3,000 to 4,000 metric tons of antimony ore.

*Italy.*—During 1900 there were 692 metric tons of antimony ore extracted from the mines at Meria, Ersä, and Luri, in the Cap Corse district north of Bastia. The bulk of the output was obtained from the Meria mines. The ores are hand picked and cobbled by women at so low a cost as to preclude even crushing machinery. The best grade of the product assays 60% metallic antimony.

*Japan.*—In recent years the production of crude antimony in Japan has fallen off considerably owing to the competition of the refined product of China. To counteract this effect a new refining plant on modern principles has been constructed near Osaka. The output of antimony in Japan is derived chiefly from the mines at Nara, Ehrme, and Yamaguchi, about 25 miles from Kyoto. The

THE WORLD'S PRODUCTION OF ANTIMONY IN METRIC TONS.

production of antimony metal during 1900 was 349 metric tons, and the exports amounted to 377 metric tons.

*Nova Scotia.*—The St. Helens Metal Recovery Co. is erecting a 30-ton plant at West Gore, and will purchase ore as low grade as 8% Sb, allowing also for 75% of the gold content. The McDougal mine has been intermittently worked from 1880 to 1892, when it was closed down. The ore is stibnite associated with pyrite, arsenopyrite, and galena, and occasionally with the oxidized antimony minerals, valentinite and kermesite. Several analyses of second grade ore showed from 1.14 to 41.13% Sb and from \$1.50 to \$80 gold per ton, the average being 12% Sb and from \$20 to \$30 gold per ton. The 3,000 tons of ore shipped pre-

viously to 1892 is reported to have averaged 12% Sb and from 2 to 3 oz. gold per ton. Several shafts have been sunk to nearly 200 ft., and 76,000 sq. ft. of ground on the vein have been stoped. Formerly only high-grade ore of 50% Sb content was shipped.

*Peru.*—The exports of crude antimony from Mollendo during 1899 amounted to 67 metric tons, which were shipped for the most part to England.

*Servia.*—A French company, with offices in Paris, is operating the antimony smelting works of Kostajnik, on the Drina river, in the western part of the country. Work has been actively carried on for several years, and the annual capacity of the works amounts to about 600 metric tons of product.

*Spain.*—The San José and the Genara mines, near Villabarcú, in the Caurel range of mountains, produced over 40 tons of concentrated antimony sulphide during 1900. The ore carries a certain amount of silver, and the mining rights cover areas of 162 and 337 acres, respectively. Antimony ore is also found in the Caurel mine, in Caurel, and at the Perseverance mine, near Brollon. The Biobra group of mines, near Biobra, in Orense, was operated during 1898-99, and more than 80 tons of ore were extracted; later the mines were shut down, but it is stated that operations are shortly to be resumed by an English company.

*The New York Antimony Market in 1901.*—The trade in antimony metal during 1901 was rather dull, and the market had a drooping tendency. The year opened with Cookson's selling at 10c.; Hallett's, 9c.; Hungarian, Italian; and U. S. Star, at 8.75c. Prices declined slowly throughout the year, and the closing quotations were: Cookson's, 10c.; Hallett's, 8@8.25c.; Italian, Hungarian, Japanese, and U. S. Star, 7.75@8c. These figures are quoted for retail lots; larger quantities were sold at a corresponding lower figure. The consumption, though satisfactory, showed but little change from last year. Imports of ore and the United States production declined markedly, while imports of metal or regulus increased to a small extent. There has been a tendency to substitute new and cheaper grades of metal for the standard English brands. Stocks at the end of the year were comparatively small.

*Volumetric Determination of Antimony.*—A sample (0.5 to 1 g.) is treated with 50 c.c. hot water and 50 c.c. strong HCl, and heated at 70°C., 30 to 60 minutes. Filter to flask, wash with dilute HCl. Add tartaric acid to filtrate, dilute to about 750 c.c., heat to 79°C., and precipitate with H<sub>2</sub>S. Filter, wash with H<sub>2</sub>S water, transfer precipitate to precipitation vessel with the aid of hot water. The sulphide is warmed with 50 c.c. strong HCl (avoid boiling) until H<sub>2</sub>S is no longer evolved. The presence of H<sub>2</sub>S is at once detected, if a little cold water be added to the solution, by the reappearance of a precipitate of red Sb<sub>2</sub>S<sub>3</sub>, the addition in the absence of H<sub>2</sub>S causing only a slight milkiness, due to basic chloride. When all H<sub>2</sub>S is expelled, the liquid is diluted, the turbidity is removed by just sufficient HCl added drop by drop, and the solution titrated with potassium permanganate.

If 5.27 g. of KMnO<sub>4</sub> be dissolved per liter of solution, 1 c.c. will equal 1% Sb with 1 g. sample. The end point of reaction is sharply defined.

*Atomic Weight of Antimony.*—G. C. Friend and E. F. Smith<sup>1</sup> have determined the atomic weight of antimony by passing dry hydrochloric acid gas over 3 g. purified potassium antimonyl tartrate contained in a protected porcelain crucible, which, after half an hour, was heated to redness. The results were remarkably concordant, and averaged 120.353, hydrogen being taken as 1.

*Alloys.*—Henry Fay and Harrison Everett Ashley (a paper read before the American Institute of Mining Engineers, November, 1901) suggest that on account of the close similarity of the physical properties of tellurium and antimony the former might replace antimony in some of its alloys. The effect of small quantities of antimony on malleable metals, such as copper and gold, renders them hard and brittle, but on lead it imparts the necessary hardness for type metal. With tin it produces valuable alloys, as Britannia metal, and with tin, zinc and copper it forms Babbitt metal for anti-friction bearings. The eutectic mixture of lead and antimony (12% Sb) resists the corrosive action of sulphuric acid, and is used for lining the lead chambers for the manufacture of that acid.

In like manner, tellurium hardens other metals, particularly lead alloys. The freezing temperature of the alloy, Sb<sub>2</sub>Te<sub>3</sub> (38.63% Sb and 61.37% Te) yielded the maximum of 629°C.; the freezing points of the two components being antimony, 624°C. and tellurium, 446°C.

<sup>1</sup> *Journal of the American Chemical Society*, July, 1901, p. 502.

## ARSENIC.

THE two most important features of the arsenic industry during 1901 were the production of 300 short tons of arsenious oxide by the Puget Sound Reduction Co., at Seattle, Wash., and the decision to close the Devon Great Consols mine, near Tavistock, which has been the chief arsenic producer in England for many years. The main supply of arsenic in the world previous to 1901 was derived almost entirely from the mines in England and Germany. The development of the industry in Canada, which produced 695 short tons in 1901, and the inception of the industry in the United States, as mentioned above, are significant factors in forecasting the future for this branch of the mineral industry.

The consumption of arsenic and arsenical compounds in the United States is indicated by the imports of white arsenic (arsenious oxide, metallic arsenic, and arsenic sulphides in recent years, which are reported in total values as follows: 1896, 5,813,387 lb. (\$215,281); 1897, 7,242,004 lb. (\$352,284); 1898, 8,686,681 lb. (\$370,347); 1899, 9,040,871 lb. (\$386,791); 1900, 5,765,559 lb. (\$265,500); and 1901, 6,989,668 lb. (\$316,525).

(a) From official reports of the respective countries. (b) Arsenious acid. (c) Metallic arsenic and arsenious acid. (d) Arsenic sulphide. (e) Arsenious acid.

**Market Conditions.**—The price for white arsenic at New York varied during 1901 from 4-5c. per lb. in January to 3-5c. in December, the monthly average for the year being 3-92c. Red arsenic from Germany was quoted at 7@7-25c. per lb. in January and February, and at 7c. for the balance of the year, averaging throughout 7-04c. per lb. at New York. Pure Paris green in bulk sold at 12@12-5c. per lb.

*Canada.*—The production of arsenious oxide in Canada during 1901 was 695 short tons, valued at \$41,676, as compared with 303 short tons, valued at \$22,725 in 1900. The entire production was made by the Canadian Gold Fields, Ltd., at Deloro, Ont., in connection with the treatment of arsenical gold ores by the bromo-cyanogen process. The concentrates, after the extraction of the gold contained in them, are passed through a cylindrical washer and the arsenical fumes condensed in suitable chambers. The collected fumes are refined in a reverberatory furnace of special design and the resultant arsenious oxide fumes are condensed and collected in a second set of chambers, yielding a product containing 99.4%  $\text{As}_2\text{O}_3$  of pure white color. Practically all of the arsenious oxide produced at the Deloro works is sold in New York. Despite the claim that Canada can produce arsenic at a lower cost than any other country, the Dominion and Provincial Governments have agreed to give a bounty of \$200,000 to aid the industry, and it is fair to assume that the production during 1902 will be greatly stimulated.

Apart from the arsenic and arsenical ores occurring in the United States, there are several chemical and metallurgical by-products rich in arsenic—as speiss from the lead smelters and precipitated arsenic sulphide produced in the purification of sulphur dioxide gas, used in the manufacture of sulphuric acid—which should be utilized in some way to replace the large quantities of arsenic compounds that are imported annually from Europe and Canada.

*Portugal.*—Arsenious oxide has been produced from arsenic ores of the Pintor mine, Oliveira, in the district of Aveiro, in the following quantities: 1898, 751 metric tons (\$65,000); 1899, 1,082 metric tons (\$56,657); 1900, 1,000 metric tons (\$71,280); and 1901, 1,010 metric tons (\$72,350). There is a small importation of arsenic from Germany, which is sold at \$35@ \$40 per ton.

*Spain.*—The San Miguel mine, near Bustarviejo, in the Province of Madrid, has lately been sold to Don Lorenzo Lulle. This property includes a large deposit of arsenical pyrites which was worked long ago as a silver mine, but subsequently abandoned; later an English company operated it for a time and produced commercial arsenic, but the venture did not prove profitable. With the recent increase in the demand for arsenic and in the price of the metal, it is believed that the property can be operated profitably. The arsenical gold pyrites of the Corunna district average about 20% arsenic and from 10 to 16 dwt. of gold per ton. This property is now being examined for Cornwall capitalists largely interested in the arsenic trade, and the results promise to be of satisfactory nature, as both the gold and the arsenic can be regained. The Métallurgique Hispano-Belge Co. has been recently formed with a capital of \$200,000 to operate the auriferous arsenical pyrites deposits near the town of Ferrol, San Vicente de Meirás; the Josefina and Josefina II. mining concessions comprise in all an area of more than 600 acres. A smelting plant has been erected at Badalona, 4 miles from Barcelona, to treat arsenic, lead and copper ores of the district. A separate department is devoted to the treatment of 30 tons of arsenical ore daily. The ore assays 45% As, and from 0.5 to 0.8 oz. gold per ton; galena also occurs in veins containing 53% Pb, 60 oz. silver, and 0.6 oz. gold per ton.

*United Kingdom.*—The Great Devon Consols mine, near Tavistock, which has been the chief producer of arsenic in England for many years, is being closed. The mine has been worked continuously at least since 1844, and the company has distributed dividends equal in the aggregate to nearly twenty-five times the amount of capitalization. The reasons given for closing the mine are the low price of arsenic and the refusal of the ground landlord to renew the lease.

*Electric Furnace Treatment of Arsenical Pyrites.*<sup>1</sup>—The Arsenical Ore Reduction Co., of Newark, N. J., has been experimenting with the Westman furnace for the electric reduction of arsenic from mispickel ores. The theory of the process is to subject the ore, a sulpho-arsenide of iron ( $\text{FeS}_2$ ,  $\text{FeAs}$ ) to the heat of the furnace in an atmosphere of nitrogen. The decomposition under these conditions causes the iron to form a fusible mono-sulphide ( $\text{FeS}$ ), which is removed as molten matte while the arsenic is distilled and condensed as a fine powder. The furnace is charged through an air-tight hopper at the top, and the nitrogen and arsenic gases are made to circulate by means of a small fan alternately through two sets of condensers, one at each end of the furnace, thus avoiding the excess heating which would result if one set only were used. An alternating current is passed through two iron electrodes to the matte, which, when molten, is a fairly good conductor. Carl Hering, from his experiments with this furnace, estimates that the cost of producing arsenic at Niagara Falls, N. Y. (electric energy at \$20 per kilowatt year) from mispickel ore containing 46% As, would be less than 25c. per hundredweight.

*Analytical Determination of Arsenic.*—S. Avery and H. T. Beans<sup>2</sup> determine soluble arsenious oxide in Paris green by digesting for five minutes over an open flame 1 g. of the sample with 25 c.c. of sodium acetate solution containing 12.5 g. of the crystallized salt; the cooled solution is diluted to 100 c.c., half of which is filtered off and titrated with standard iodine in the usual way. The study of the action of carbonic acid on Paris green suspended in water showed that the usually accepted maximum amount of arsenious oxide (4%) permissible in Paris green to be used for spraying purposes is a false guide as by hydrolysis and the action of carbonic acid, much of the arsenic in the Paris green is converted into the soluble condition, a fact that explains many of the irregularities observed in the action of Paris green on foliage, as weather conditions might have favored the formation of free arsenic trioxide from a comparatively pure sample of Paris green.

*Electrolytic Process for Making Paris Green.*—Richard Franchot, of Niagara Falls, has patented a process<sup>3</sup> for the manufacture of Paris green by electrolyzing with a copper anode a solution of calcium acetate and arsenious acid.

<sup>1</sup> *Electrochemist and Electroplatingist*, October, 1901.

<sup>2</sup> *Journal of the Chemical Education Society*, February, 1901.

<sup>3</sup> United States Patent No. 686,684.

## ASBESTOS.

THERE was a considerable decrease in the production of asbestos in the United States during 1901 from the previous year, the output being 747 short tons, valued at \$13,498, as compared with 1,100 short tons, valued at \$16,500 in 1900. The value of the product during 1901 is reported at 20% increase above the price for 1900. Practically the entire output was derived from the mines of the Sall Mountain Asbestos Co., at Sall Mountain, White County, Ga., there being but a very small quantity produced by the Berkshire Talc Mining Co., at Hinsdale, Berkshire County, Mass., and by the Pacific Asbestos Co., at Riverside County, Cal. Deposits of asbestos of the chrysotile variety have been reported near Grants Pass, Ore., west of Sims Station, Cal.; near North Wilkesboro, N. C., and near Toccoa, Ga. In Wyoming, the McConnell Asbestos Co., of Pittsburg, Pa., is actively engaged in developing its mines. The H. W. Johns Manufacturing Co., of New York, and the Mannville Covering Co., of Milwaukee, Wis., consolidated their interests on January 1, 1902, under the name of the H. W. Johns-Mannville Co., with a capitalization of \$3,000,000. The new company is constructing a plant at Milwaukee for the manufacture of mineral wool and calcined magnesite for special use as non-conducting coverings for boilers, steam pipes, etc.

The price for crude asbestos in the United States during 1901 showed a marked advance from the average price of the preceding year, which was due to the control of the market having been acquired by one manufacturing company in the United States.

### PRODUCTION AND IMPORTS OF ASBESTOS IN THE UNITED STATES.

| Year.     | Production. |              |          |                       | Imports.      |                 |           |

(a) From official reports of the respective countries. (b) Not stated in the reports. (c) Exports.  
(d) Statistics not yet available.

A comparison of the output of the United States with the quantity of asbestos reported shows the very small proportion of the domestic consumption that is derived from domestic sources. The active developments of asbestos mines in the United States during 1902, notably at Eden and Lowell, Vt., and at Caspar, Natrona County, Wyo., will reduce considerably the ratio of the imported mineral product. In Vermont there are four companies engaged in developing asbestos mines: the New England Asbestos Mining & Milling Co., the National Mining & Development Co., the Tucker Asbestos Co., and the Vermont Asbestos Co. The first named concern has made the most progress, and it is reported by Dr. Joseph Hyde Pratt to have 20,000 tons of asbestos rock on the dumps ready for milling.

The name asbestos is given to the fibrous variety of the minerals amphibole, a calcium and magnesium silicate, and serpentine (chrysotile), a hydrous magnesian silicate. The fibers of the latter, though shorter, are up to 2 in. in length, and are superior in strength and elasticity, consequently the field for its use is much larger. The fibers of the amphibole variety are sometimes 3 ft. in length. Practically all of the chrysotile variety consumed in the United States and Europe is obtained from the noted deposits at Black Lake and Thetford, Sherbrooke County, Ontario, Canada.

The chief use for asbestos is as a non-conductor of heat for boiler covering; fireproof paints for wall plaster; packing for fireproof safes, etc. When non-conductivity of heat and not strength of fiber is required the amphibole variety can be used, but when strength of fiber also is essential, as in the manufacture of cloth felt board, rope blocks, etc., the chrysotile variety is used. Recently asbestos has been used in the manufacture of fireproof bricks, and tests made by the British Fire Prevention Committee (*Stone*, February, 1901) on "gypsine," a fireproof material composed of hydraulic lime, sand, and asbestos pressed into bricks, showed remarkably good results. One side of a 9-in. partition of gypsine bricks set in hydraulic mortar and lightly coated with a layer of fire clay, was submitted for an hour to a temperature which rose to 2,050° F. The material was in no way affected, and the temperature of the outer surface was never sufficiently high to ignite a match held against it.

*Canada.*—The production of asbestos in Canada during 1901 showed a very large increase over the figures for 1900, both in quantity and value, being 38,097 short tons, valued at \$1,186,434, as compared with 29,141 short tons valued at \$748,431 in 1900. The variation in the average value per ton is due to the large quantity of asbestic and low-grade fiber that is included in the total output. Of the total production of asbestos in Canada during 1901, the following quantities expressed in short tons were exported: 18,117 to the United States; 3,324 to the United Kingdom, 2,235 to Germany, 2,221 to Belgium, 240 to France, and 588 to other countries; making a total of 26,715 short tons, which is equal to 81% of the total output.

## ASPHALTUM.

UNDER this heading are included all mineral bituminous products embracing as well that portion of the residuum from the refining of petroleum which is sold and used as asphaltum.

### PRODUCTION OF ASPHALTUM AND BITUMINOUS ROCK IN THE UNITED STATES. (IN TONS OF 2,000 LB.)

(a) Statistics of the California State Mineralogist. (b) Includes 1,000 tons of liquid asphaltum valued at \$49,850. (c) Estimated. (d) Includes production in Indian Territory.

The production of bituminous sandstone in the United States during 1901 was practically the same as in 1900, the quantity and value being 34,248 short tons (\$138,601), as compared with 34,277 short tons (\$138,892) in 1900. Practically the entire output was produced from California. The quantity of bituminous limestone produced in 1901, from the deposits of Indian Territory and Texas, amounted to 6,970 short tons, valued at \$33,375, as compared with 3,910 short tons, valued at \$16,830 in 1900, showing a very large increase. The production of asphaltum in California during 1901, including 1,000 tons of the liquid product valued at \$49,850, was 19,988 short tons (\$316,559), as compared with 11,140 short tons (\$218,520) in 1900. The quantity of gilsonite produced in 1901 is estimated at 1,500 short tons, valued at \$46,000, as compared with 3,279 short tons, valued at \$98,370 in 1900.

The National Asphalt Co., which was incorporated in 1900 with a capitalization of \$22,000,000, divided into 200,000 \$50 shares of 6% cumulative preferred stock and 240,000 \$50 shares of common stock, was declared insolvent December 28, 1901, and was placed in the hands of receivers. The chief cause assigned for the failure of the combination was the keen competition with which the subordinate companies had to contend, and which left them unable to pay dividends upon their stock, nearly all of which is held by the National Asphalt Co. It is reported that the company will be reorganized on a basis of \$25,000,000 stock, of which \$15,000,000 is to be preferred and \$10,000,000 common.

An interesting note on the use of asphaltum for pavement is the utilization of fine stamp mill tailings from the treatment of copper ore at Lake Superior as a constituent for the paving mixture, which consists of 70% sand tailings, 15% limestone, and 15% asphaltum cement. One pavement company reports the use of 15,000 long tons of the material in 1900, and 20,000 long tons in 1901.

The development of the asphaltum industry in the United States is well set forth in the paper on "The History of the Asphaltum Industry," given later in this section.

THE WORLD'S PRODUCTION OF ASPHALTUM AND ASPHALTIC ROCK. (a) (IN METRIC TONS.)

NOTE.—There is a considerable production of asphaltic stone in Switzerland of which no account is taken in the above table, the Swiss Government not publishing any mineral statistics.

#### ASPHALTUM IN FOREIGN COUNTRIES.

*Cuba.*—The following brief summary of the asphalt deposits of Cuba has been largely obtained from an article in the *Engineering and Mining Journal*, March 8, 1902, entitled "Bitumen in Cuba," by T. Wayland Vaughan. The deposits of asphalt generally occur as veins, pockets or exudations in the form of springs, usually in serpentine rock, but occasionally in limestone. None of the material is now found in its original rock, and it is not at present possible to state from what rock this material has been derived. Bituminous substances, asphalt and mineral tar are found in every province, and the material is generally suitable for use as varnish or as insulating material. Most of the deposits, how-

ever, contain too much asphaltene for use in paving or roofing. While some of the deposits contain large amounts of petroleum, whether or not it is in stable chemical combination has not been definitely determined. It has been suggested that the glauconitic pitches containing large proportions of asphaltene might be mixed with maltha containing a large proportion of petroleum and so make a material suitable for paving.

Province of Pinar del Rio.—The Santa Helena deposit, at Bahia Honda, is said to be of great purity and abundance, and extensive deposits are reported in the Vuelta Abajo district. The Rodas Concepcion and Magdalena mines, at the head of the Bay of Mariel, operated for a number of years, have produced from 1,000 to 1,300 tons annually, all of which has been consumed for fuel or for gas making on the estate of the owner, Don Ramon Balsinde. The deposits are about 36 ft. thick for over 100 ft. in length. A deposit of asphaltum about one mile south of Mariel Bay, which has been quarried to a depth of 50 ft., is a brownish, impure, solid asphalt. Near Banes, between Mariel and Habanas, the San José and Constancia mines have not been worked extensively.

Province of Havana.—The Casualidad asphalt mine is situated 6 miles from Guanabacoa, 9 miles east of Havana, and 2 miles south of the sea. The asphalt occurs in serpentines, diorites, and euphotides, accompanied by veins of quartz and chalcedony, and often copper. The outcrop is traceable for a distance of from 600 to 900 ft. At the surface, the vein was about 1 ft. thick, while at 30 ft. depth it is 9 ft. thick. An analysis shows: Carbon, 34.97%; volatile matter, 63%; ashes or cinder, 2.03%. Specific gravity in three different specimens, 1.142, 1.189, 1.197; streak, dark; powder, brown. The property has not been worked to any great extent and the demand for its products appears to have been limited. The Prosperidad, 6 miles from Havana, on the road to Taposte, has been explored to a depth of 144 ft. by two shafts, and numerous galleries show a horizontal extent of 180 ft. Four other mines near Havana have been worked some years ago, but scarcely more than 600 tons of material were recovered from them. The only mine in the province which is now being operated is the Angela Elmira, located about 5 miles from Bejucal and owned by the West Indies Co., of New York City. The mine was reopened in the latter part of 1900, and regular shipments were made during 1901 to various parts of the United States. The asphalt is hard, occurs in a good sized body in limestone, and carries from 70 to 72% of bitumen. The full analysis made by Dr. L. Saabach is: Moisture and volatile at 60°C., 2.4%; petroleum, 34.6%; asphaltene, 38.1%; non-bituminous organic matter, 5.4%; silica, 10.2%; iron and alumina oxides, 4.9%; lime, 1.7%; magnesia, 0.2%; sulphur, in mineral combination, 2.4%; alkalis and undetermined, 0.1%.

Province of Matanzas.—About 10 miles northwest of Matanzas, asphalt exudes from small fissures in serpentine on a contact with hard blue limestone, the serpentine forming the hill and the limestone lying on its flank. The deposit has not been developed to any great extent. Another occurrence of asphalt is reported near Guamacaro, between Limonar and Cárdenas, in Cárdenas Bay. There are four asphalt deposits of two grades. The one in the western portion of the bay has been worked for 21 years, and produces a very fine grade of asphalt, which

is used in the United States for the manufacture of varnish, and commands from \$80 to \$125 per ton of 2,240 lb., delivered in New York City. About 1.5 tons are obtained daily by means of submarine work. A lighter being moored over the 125-ft. shaft, a long pointed iron bar manipulated by a winch is dropped into the shaft repeatedly until a sufficient quantity of the asphalt has been broken, when a diver is sent down to fill a basket with the material thus acquired. The three other mines yield asphalt of a lower grade, suitable for roofing or paving purposes only. No. 4 mine, situated near Diana Cay, 15 miles from Cárdenas, is called the Constancia, and about 20,000 tons have been taken from it during the 20 years of its operation, without any apparent exhaustion of the deposit, which is inclosed within a circle of about 150 ft. diameter. As the depth of water is but 12 ft. about 30 tons per day is obtainable using primitive methods only. Near Sabanillo de la Palma, 30 miles east of Cárdenas, a thick mineral tar oozes into a well sunk into serpentine rock for about 80 ft. in depth. The material is recovered by hand windlass and bucket at the rate of about 20 bbl. per day. Two other tar wells are close at hand and about 1 mile southwest is another area of natural tar springs, one of which has been explored to a depth of 60 ft. One of these wells fired during the last insurrection, burned for four months before it was put out by a heavy rain, and the ground for about 80 ft. about this hole is at present covered with coke. Another tar hole occurs near the Santa Catalina plantation, about 5 miles from the northern coast.

Province of Santa Clara.—The Santa Eloisa asphalt mine, near Loma Cruz, about 9 miles northeast of Santa Clara, is a deposit, about 20 m. deep, by 40 m. wide of unproved length, which exists in a cavity in serpentine rock. The material is a hard glance pitch, and is used in Santa Clara for the manufacture of gas. The following analysis, made by Mr. Frederick P. Dewey, is unfortunately not expressed in terms of asphaltene or petrolene, although the volatile matter may be reckoned as petrolene, and the fixed carbon as asphaltene: Moisture, 1.28%; volatile matter, 45.43%; fixed carbon, 31.75%; ash, 21.54%. Several deposits of more or less liquid asphaltum exist in the vicinity of Camajuani, about 18 miles from Santa Clara, and a deposit of solid asphaltum is known near the Sagua river, about 3 miles from Ranchuelo. Three other deposits are reported in the province.

Province of Puerto Principe.—Both asphaltum and mineral tar have been mined to a limited extent in this province. The present cost of getting the asphalt from the mines to El Estero, Reá, is estimated to be about \$13 per ton.

Province of Santiago.—A deposit of solid asphalt, a glance pitch, exists near Puerto Padre, but little or no work has been done to develop it.

Germany.—The production of asphalt in Germany during 1901 was 90,193 metric tons, as compared with 89,685 metric tons in 1900.

Italy.—Italy exported 21,856 metric tons of asphalt during 1901, a decrease of 2,431 metric tons from the export of 24,287 metric tons in 1900.

Madagascar.—Samples of liquid asphalt have been sent to the French colonial office by General Galliene from Ambodiriana, near Ankely Marobaola. The deposit is of very limited extent.

Mexico.—According to Alejandro Prieto, in his *History of Tamaulipas*, large

quantities of asphaltum occur in the State along the interior margins of the Laguna Madre, Morales, and in the vicinity of Sota La Marina. In some asphaltum beds (chapopote) the asphalt is of a dark chocolate character and in a somewhat liquid form, while in others it is an ebony-black color in a compact, solid form, resembling coal. The surface appearance of these deposits indicates the presence of petroleum also.

*Trinidad and Tobago.*—The exports of asphalt from the Island of Trinidad are given in the following table, for which we are indebted to the courtesy of Mr. Ira Atkinson, treasurer of the New Trinidad Lake Asphalt Co., Ltd. Seven-eighths of the asphalt exported is dug from Pitch Lake, which is leased to the company for a term, of which 28 years have yet to run. Despite the removal of 1,720,000 long tons of asphalt during the past 34 years, there has apparently been very little impression made on the Pitch Lake deposit. The greater bulk of the exports is made by the New Trinidad Lake Asphalt Co., although some 30,000 tons are annually handled by smaller shippers from lands outside the lake. The lake contains no liquid asphalt, but in other parts of the island this variety, from which illuminating and lubricating oils can be distilled, is found widely distributed. Glance pitch, also found in the island, is used for electric insulations and for black varnishes. Manjak, another variety, has recently been discovered in quantity, about 10 miles north of the pitch lake.

(a) The exports prior to 1897 will be found in THE MINERAL INDUSTRY, Vol. VII. (b) Included in the shipments of crude.

*Venezuela.*—The right of the Warner Quinlan Syndicate, of Syracuse, N. Y., to operate the asphaltum deposits in the Department of Sucre is still in litigation, and while the Province court at Carupano annulled the concession formerly granted to the New York & Bermudez Co., the matter has been carried on appeal to a higher court. An occurrence of asphaltum has been reported by Mr. R.

Zuber, of London, on the Island of Pedernales, in the Orinoco delta. The deposit is reported to be similar to the asphalt beds of the Island of Trinidad and of an extent to permit an annual extraction of 20,000 tons for some years to come.

#### OZOKERITE.

In describing the ozokerite industry of Boryslaw, Galicia, F. W. Hossfield states that an attempt has recently been made to form an ozokerite trust which will embrace under one management all the existing mines and mineral leases of mines known or supposed to contain deposits of mineral wax, but owing to the obstinacy of the owners of some smaller tracts, the promoters of the trust have not as yet been successful. The area of the ozokerite beds of Galicia cover 957 sq. miles, and from the latest official report (1898), there were 42 companies engaged in the field, employing 5,413 operatives. The output in that year amounted to 17,068,290 lb. The mineral wax is never found in a pure state, and the material for export is usually freed from earthy matter near the mines. The purifying process is quite simple and consists in placing the material in tanks which are heated either by direct fire or by steam. When direct fired the flames must heat the sides as well as the bottom, otherwise the wax will become overheated and partial distillation will ensue. At the later works steam heat is now used for refining purposes. At first the steam must possess sufficient heat to melt the wax, but when overmelted a much smaller amount only is required to maintain the product. The liquid condition is then continued until the impurities settle to the bottom. The wax is then drained into iron vessels having the form of a cone and previously lime washed to prevent the adherence of the congealed blocks of wax. The blocks weigh from 650 to 850 lb., and are generally from 15 to 25 in. high, with a maximum diameter of from 30 to 36 in. An analysis of the better quality of unadulterated Boryslaw ozokerite gave: Water, 0.33%; naphtha, 5.67%; petroleum, 3.67%; crystallizable paraffine, 82.33%; other substances, residue and loss, 8%. Ozokerite melts between 136° F. and 212° F. Blocks of the latter high degree of fusibility, however, are seldom found. The average melting point of the better qualities is from 140° F. to 158° F. If the wax melts below 136° F. it may be taken for granted that it has been adulterated with other substances. There are about 20 refineries for converting raw ozokerite, and it is doubtful if the processes employed by any two of them are identical. In most of the refining works the wax is mixed with from 6% to 10% of sulphuric acid, heated and filtered through bone charcoal or spodium, which imparts a yellow color to the product. It is again treated with sulphuric acid, and finally with caustic soda, until the acid is completely neutralized. Fairly successful experiments have also been made to avoid the use of sulphuric acid by the substitution of benzol, in which case the solvent must be eliminated by distillation. In the filtering process referred to, coal in small grains is placed between two sieves, which are inserted in each filter. A number of filters are placed together in a frame and sufficiently heated by direct steam to keep the wax in a liquid state. Whenever the coal is tested its efficacy as a bleaching agent is regenerated by a special treatment. After the mass has been decolorized it is

decanted into funnels having paper filters with a device for keeping the material heated during filtration.

In 1900 Austria exported 11,363,779 lb. crude ozokerite, valued at \$1,047,805, of which 8,326,333 lb. was shipped to Germany and 22,707 lb. to the United States. This amount, however, does not represent the total quantity shipped to the United States, as much of the product exported to Germany is again re-shipped to this country.

Exports of refined ozokerite or ceresin from Austria in 1900 amounted to 1,927,809 lb. (\$234,546) of which 308,864 lb. (\$36,261) were shipped to Germany, the direct exports to the United States being 77,381 lb. (\$3,085).

Among the new uses to which ozokerite is applied, beyond those enumerated in the preceding volumes of THE MINERAL INDUSTRY, may be mentioned in the manufacture of phonographic cylinders and in galvano plastic printing.

### THE HISTORY OF THE ASPHALT INDUSTRY TO 1901, INCLUSIVE.

BY A. W. DOW.

ASPHALT paving in this country may be said to date from the year 1870, although there were a few pieces laid before this date.

The first regular asphalt pavements in Europe were laid with a limestone rock asphalt mined at Val de Travers, Neufchatel, Switzerland, in 1856, on the Rue Bergere, Paris, by M. Vaudry; another small piece was laid in 1858 in front of the Palais Royal, on the Rue St. Honore, one of the most traveled streets in the world, and the first asphalt pavement in the city of London was laid with Val de Travers asphalt on Threadneedle street, near Finch lane, in May, 1869.

The success of these pavements in Europe attracted considerable attention in this country, but the great expense of shipping and laying the European asphalts prevented their use excepting in one or two experimental pieces. Attempts, however, were made to use coal tar mixed with mineral ingredients, and in 1867 a small portion of one of the drives in Prospect Park, Brooklyn, N. Y., was laid with a coal-tar pavement patented by Mr. Scrimshaw, followed by a similar one laid on Diamond street, near Lenox Road, Flatbush, L. I. The latter pavement lasted for more than 20 years. In the city of Washington in the early seventies several patented coal-tar pavements were laid, the great majority of which were utter failures, while some few have given and are still giving excellent service at the present date. With the paucity of knowledge of the construction and the materials used in such paving at that time, it is little wonder that there were so many failures, and it can be considered merely accidental that any of these first still remain.

In 1870 Edward J. DeSmedt procured patents for the manufacture of pavement, using Trinidad asphalt softened by heavy petroleum oil and mixed with sand and powdered carbonate of lime. Samples of this new pavement which were laid in front of the City Hall in Newark, N. J., and around his works in Jersey City, proved so satisfactory that in the next five years the American Asphalt Paving Co., The Grahamite Asphalt Co., The Grahamite Asphalt Paving

Co., and The Grahamite & Trinidad Asphalt Paving Co. were organized. The most notable successes of these various companies were the pavements laid in 1873, on Fifth avenue, between 24th and 25th streets, and in Trimble place, from Duane to Thomas streets, in the city of New York, and in front of Independence Hall, opposite the Ledger Building, in the city of Philadelphia.

The first foreign rock asphalt laid in this country was a small piece of pavement laid with Neufchatel rock asphalt in 1872, on Union Square, New York. The Neufchatel rock asphalt was also used later in several other cities to a limited extent.

In 1876 a special commission was appointed by Congress to decide on the best pavement to be used on Pennsylvania avenue, from the Capitol to the Treasury, in the city of Washington, which decided to pave from Sixth street to the Treasury with Grahamite & Trinidad pavement, laid under the supervision of the patentee, E. J. DeSmedt, using asphalt from deposits on the Island of Trinidad, and between the Capitol and Sixth street with foreign asphalt rock by the North American Neufchatel Asphalt Co.

Before the use of Trinidad asphalt for pavements it had been mined for various purposes. The tenth Earl of Dundonald seems to have first brought Trinidad asphalt into commercial notice. In 1851 he leased for 20 years a large part of the lake and some of the adjoining asphalt land, and in 1865 assigned his lease to a joint stock company called The Trinidad Petroleum Co., Ltd., organized with a view to distilling petroleum out of the asphalt. This company, which seemed not to have been prosperous, went into liquidation in 1866. Mr. Thomas A. Finlayson succeeded to its leasehold rights and continued shipping asphalt.

In the meantime other parties commenced shipping asphalt mined from deposits existing at La Brea and Point d'Ore, Trinidad. In 1871 the Governor decided to lease the asphalt lake in lots of only five acres each, when the existing leases thereon had terminated, with the result that the entire asphalt lake, with the exception of one five-acre lot, came under the control of four lessees. These lessees in time combined so as to monopolize the output of asphalt from the lake, but they still had considerable competition from parties mining asphalt in the village lots of La Brea and at Point d'Ore.

In 1878, Mr. A. L. Barber contracted with Mr. John G. Douglas, who mined asphalt at Point d'Ore, to supply him with asphalt for four years, and in 1880 visited the Island of Trinidad and succeeded in uniting all the conflicting interests connected with the shipping of asphalts, both from the lake and land deposits. But in 1886, when the Colonial Government decided to grant pitch-digging licenses indiscriminately on the five-acre lot formerly held in reserve, which could furnish as much pitch as the remainder of the lake, it is no surprise that the parties in this combination became dissatisfied, for by this procedure the lessees would be forced to do business without protection. It was again through Mr. A. L. Barber that a new contract was made with the Government carrying the exclusive right to mine asphalt from the lake and the protection of the Crown against competition from the other Crown deposits. This new deed was made in July, 1888, between the Crown, and Previte & Creig, of London, and the New York & Trinidad Asphalt Co., of New York, the latter having the exclusive right

for this country. In 1899 the licenses and privileges of the two above companies were assigned to the Trinidad Asphalt Co. This new company, although having a monopoly of the Trinidad Lake asphalt in this country, had a little competition from a few parties mining asphalt in the village of La Brea, among which were the West Indies Asphalt Co., Carter, Hawley & Co., and Christale & Co.

The Trinidad Asphalt Co. gradually acquired these out-lying deposits, until there only remains the original Dundonald holding in the village of La Brea, which is now being worked by the Warner Quinlan Asphalt Co., of Syracuse, N. Y.

In 1880 asphalt was mined in Cuba by W. S. Wilkinson, of Baltimore, Md., and Cranford & Filbert, of Washington and Philadelphia, the former manufacturing asphalt block, which proved of such poor quality that the mining was discontinued in about a year. Cranford & Filbert used it for sheet asphalt, but for various causes only one cargo of this asphalt was imported by them, and later they made a contract with the Trinidad Asphalt Co. for a supply of Trinidad Lake asphalt. The mining of asphalt in Cuba for paving was discontinued until 1901, when the mine at Bajucal, Cuba, which had been purchased by the West Indies Co., of New York, shipped asphalt for fluxing with heavy refined maltha from California into a paving cement which has been laid during the past year in the city of Washington.

Although as stated before a little paving had been done in this country with the foreign rock asphalts, yet no particular company ever did any considerable paving with these materials.

The Sicilian Asphalt Co., of New York, did some paving with a mixture of asphalt rock mined at Regusa, Sicily, and German rock asphalt, but about 1890 it entered into an agreement by which it obtained and laid Trinidad asphalt, and it is now using Trinidad asphalt in all its work. The German rock asphalt, from Limmer, near Hanover, has been used to a considerable extent in this country mixed with other rock asphalts. The asphalt rock mined at Seyssel, Department of L'Ain, France, has been laid more extensively of late than any other foreign rock asphalt by the Compagnie Generale des Asphaltes de France.

The first asphalt rock mined in this country for paving was probably that from Santa Cruz, Cal., which is there called bituminous sandstone, and was first laid in the city of Santa Cruz, in 1868, over an old wooden pavement, but was not extensively used until 1880, when several pavements were laid in San Francisco. At the present time there are several miles of this pavement in San Francisco and other cities on the Pacific slope. Other most important asphalt rocks of California are mined in San Luis Obispo County and Santa Barbara County, but the use of these asphalt rocks, owing to the expense of transportation, is confined to the cities within easy distance of the mines.

The first pavement laid with asphalt rock mined in Breckenridge County, Ky., was in the year 1890, in the city of Louisville. Since then a few miles of pavements have been laid with mixtures of this asphalt with other harder asphalt rocks richer in bitumen. The greater part of the paving done with Kentucky rock has been in the city of Buffalo, where it was laid mixed with Vorwhole asphalt rock from Germany. Other deposits of asphalt sandstone have been

opened up in Kentucky, the most important of which are at Youngs Ferry, Logan County, and at Russellville, Warren County. A little paving has been done with these rock asphalts in cities easy of access to the mines. During 1901 some of the asphalt mine interests of Kentucky have been consolidated into the Federal Asphalt Co.

In 1891 a deposit of asphalt limestone was opened up at Clein, Uvalde, Texas, by the Litho-Carbon Co., which intended to extract the bitumen from the rock and treat it by a patented process until it resembled vulcanized rubber in consistency. This company was not at all successful, and in 1896 went into the hands of a receiver. In 1898 the Uvalde Asphalt Co. secured the mine at Clein, and commenced mining asphalt for paving purposes; some few streets were laid with it, but the expense of transportation limited its use. In 1899 the company installed a plant for extracting bitumen from this rock by means of naphtha, and it is supposed did some little paving, but the process proved so expensive that it was abandoned, and for the past three years the Uvalde Co. has been using asphalt secured from the Trinidad Asphalt Co. During the past year the Uvalde Co. has secured a deposit of asphalt on Lake Maracaibo, in Venezuela, where it has put up an extensive refinery, and expects soon to begin shipping asphalt to this country.

Some paving has been done in St. Louis and other Western cities with asphalt rock from Indian Territory. In the Buckhorn district, about six miles from Dougherty, the most extensive deposits of the Territory are controlled by the Gilson Asphaltum Co., of St. Louis, Mo., which mines both sandstone and limestone impregnated with asphalt, mixing these rocks about half and half for paving.

About 1890 the California Petroleum & Asphalt Co. was organized in California, to mine a hard asphalt at La Patera, Ventura County, and as a flux it extracted a thick maltha from the bituminous sand at the La Conchas mine, at Carpentera. This combination was called Alcatraz asphalt, which name was afterward adopted by the California Petroleum & Asphalt Co. The Alcatraz Asphalt Co. came East with its material about the year 1893 and commenced a strong competition with Trinidad asphalt. It was not long before the mine at Carpentera was exhausted and the La Patera mine was worked to such a depth that it became expensive mining, when the Alcatraz Co. procured its asphalt by evaporating the asphaltic petroleums of California until they were of the consistency of asphalt, to which it gave the name of Grade "D" asphalt. This was not entirely satisfactory, so it attempted the extraction of asphalt from the asphalt sandstone found on the Sisquoc ranch, Santa Barbara County, Cal. The asphalt in a naphtha solution was conveyed by pipe line to the coast, where the naphtha was evaporated and returned to the refinery. This process in turn proved so expensive that it was soon abandoned, and it is said that the company now gets its asphalt from the Harris mine, Santa Maria, Cal. In 1899 the Alcatraz Co. was absorbed by the Asphalt Co. of America, and of late it has done little or no paving excepting on the Pacific coast.

About the time that the California Petroleum & Asphalt Co. was developing its Alcatraz asphalt a company was organized in Kern County, Cal., which mined,

at Asphalto, about 20 miles from Bakersfield, Kern County, an asphalt which is quite hard, and which was fluxed with a heavy maltha obtained from wells in the neighborhood of the mine. This new company, the Standard Asphalt Co., of California, in the year 1894 began introducing its material in the East in competition with the Trinidad asphalt interests, which was continued until it was bought in by the Trinidad interests about the year 1897.

In 1892 Mr. Thomas H. Thomas, of New York, obtained a grant of land from a Mr. Hamilton, for mining asphalt on a concession which the latter had obtained from the Venezuelan Government. This deposit, which is situated at Guanoco, Province of Bermudez, is generally known on the market as the Bermudez asphalt. Mr. Thomas organized the New York & Bermudez Co., and commenced the laying of pavement with this asphalt fluxed with petroleum residuum, under the supervision of Mr. E. J. DeSmedt, and so successfully competed with the Trinidad Lake interests that it was bought up by the Barber Asphalt Paving Co., in 1896.

The mining of asphalt from the Bermudez deposit was carried on by the New York & Bermudez Co. without opposition until 1900, when a portion of this deposit, which is known as the Felecidad, was sold by the Venezuelan Government to Mr. Sullivan, of the Warner Quinlan Asphalt Co. Through this transaction arose the dispute so much discussed of late between the New York & Bermudez Co., or, in other words, the Asphalt Trust, and the Warner Quinlan Asphalt Co. This dispute is still before the courts of Venezuela.

A deposit of asphalt was developed at Tuxpan, Mexico, by the Mexican Asphalt Co., of Chicago, in the year 1896, which did some little paving with it in Chicago. A refinery and paving plant was built in Jersey City, N. J., by this company for the handling of its asphalt, but it is doubtful whether any of it was laid from this plant, and it is generally understood that Trinidad asphalt has been used. In 1900 this company was bought in by the National Asphalt Co.

For over ten years gilsonite, a pure, hard asphalt, has been mined in Uinta County, Utah, for various purposes, but it was not until the year 1898 that the Gilson Asphaltum Co., of St. Louis, Mo., commenced its use for paving. This asphalt was fluxed with heavy California maltha until of a proper consistency for a paving cement known on the market as Buena Vista asphalt. Pavements have been laid with this material in St. Louis and other Western cities. The Gilson Asphaltum Co. was bought in by the Asphalt Co. of America in 1899. Shortly before the introduction of the above asphalt for paving by the Gilson Asphaltum Co., the Assyrian Asphalt Co., of Chicago, commenced its use by fluxing it with Eastern petroleum residuum, and in some cases it has fluxed it with a flux manufactured under the Culmer patent by blowing air into petroleum residuum. The pavements made of this material did not prove all that could be desired, and I believe that it has discontinued the use of this asphalt.

Beside the natural asphalts, there have been used for paving artificial asphalts manufactured from oils. About the first manufactured asphalt on the market was known as Pittsburg flux, which was made by a process patented by Mr. J. A. Dubbs, in 1892, by heating Eastern petroleum residuum with sulphur at a high

temperature. The product obtained resembled a wax more than an asphalt, and with the exception of one street, laid in Pittsburg, it was never used by itself for paving. It was bought a few years later by the Barber Asphalt Paving Co., and used as a flux which gave a desirable property to the resulting asphalt cement when mixed with Trinidad asphalt.

In the year 1894 Mr. F. X. Byerley, of Cleveland, Ohio, procured a patent for the manufacture of an artificial asphalt from petroleum by the oxidation of petroleum residuum by blowing air into it while heated at a high temperature. The material resulting from this process was a poor imitation of asphalt, and, although some few pavements were laid with it, they have not proved of desirable quality. About 1896 Mr. J. A. Dubbs applied his process of heating oils with sulphur to the California asphalt oils and commenced the manufacture of an artificial asphalt under the trade name of Ventura Brand California Asphaltum. The California Asphaltum Co. manufactured this product at its refinery at Ventura, Ventura County, Cal. Considerable of this asphalt was used throughout the country, principally in Pittsburg and Allegheny. In 1899 this company and its patent were bought out by the Asphalt Co. of America.

The Los Angeles Oil Burning & Supply Co. erected a refinery in Los Angeles, Cal., for the manufacture of asphalt from the oils of that neighborhood by simply distilling off the light oils. This company reorganized in 1896 under the name of the Western Oil & Asphalt Co., and continued the manufacture of asphalt under this name until it was bought out by the Asphalt Co. of America in 1899. The president of the Western Oil & Asphalt Co. soon after this organized a new company which is now manufacturing asphalt from oil in Los Angeles, under the name of the Southern Refining Co.

The Union Oil Co., of California, has been manufacturing from oil an asphalt for paving which it calls Diamond Asphalt.

Of late there have been several companies organized for the manufacture of asphalt from California oils, among which may be named, Jewett & Blodgett, the Pacific Refining Co., of Bakersfield, Cal., and the Ojai Asphalt Co., of Santa Paula, Ventura County, Cal.

#### THE PRESENT CONDITION OF THE ASPHALT PAVING INDUSTRY.

The most important company at the present time is the National Asphalt Co., or what is popularly known as the Asphalt Trust, which was organized in 1900 by John C. Mack, of Philadelphia, and first consisted of the Mexican Asphalt Co., of Jersey City, the Hudson River Stone Co., and several minor companies controlled by Mr. Mack. Shortly after its organization it absorbed the Asphalt Co. of America, which was then known as the Asphalt Trust. The principal companies composing the Asphalt Co. of America were the Barber Asphalt Paving Co., Warren Scharf Asphalt Co., New York & Bermudez Asphalt Co., the Alcatraz Asphalt Co., the Gilson Asphaltum Co., Standard Asphalt Co. of California, the Trinidad Asphalt Refining Co., and the Columbia Construction Co. Among the other important companies beyond the control of the National Asphalt Co. are the Warner Quinlan Asphalt Co., of Syracuse, N. Y., using asphalt mined from

the Dundonald Estate on the Island of Trinidad. This company is supplying several companies with asphalt. The Globe Asphalt Co., having its refinery at Obispo, Cal., is supplying companies throughout the country with asphalt. Its Eastern agent is the Inter-State Paving Co. The Warren Asphalt Co., of Utica, N. Y., is supplying Warren's Acme California Asphalt, manufactured in Los Angeles, Cal. The Southern Refining Co., of Los Angeles, Cal., is supplying Southern Cross Asphalt, manufactured in Los Angeles, Cal., and the West Indies Co. is furnishing Cuban asphalt fluxed with Californian maltha. There are several other companies supplying both asphalt and asphalt rock.

The asphalt block industry, with a few minor exceptions, obtained its supply of asphalt from the International Paving Co., which, by a special contract made by its president at the time of the formation of the Trinidad Asphalt Co., buys Trinidad Lake asphalt from the latter company.

During the past year a new patented pavement has been brought out by the Warren Brothers Co., of Boston, Mass., which is known as bituminous macadam, and is made by binding together stone graded from about 1.5 in. in size to an impalpable dust, with a specially prepared bitumen manufactured from coal tar. Several pavements of the above class have been laid throughout the country during the past year.

## BARYTES.

THE production of barytes in the United States during 1901 amounted to 49,070 short tons valued at \$157,844, as compared with 41,466 short tons valued at \$194,178, in 1900, showing an increase of 7,504 short tons. As in recent years the supply was obtained from Missouri, Virginia, Tennessee, North Carolina and Georgia in the order of their production. The mineral is mined chiefly in open cut as shaft sinking is too costly at the present price of the product. Barytes occurs in many other States, notably Arkansas, Connecticut, Delaware and Kentucky, but no output was obtained from these deposits during 1901. In some instances, however, a small amount of development work has been accomplished.

The following tables give the production, imports and consumption of barytes in the United States from 1897 to 1901 and the world's output for the years 1896 to 1900, inclusive.

### PRODUCTION, IMPORTS, AND CONSUMPTION OF BARYTES IN THE UNITED STATES.

(In tons of 2,000 lb.)

| Year.     | Production. |                |           | Imports.  |                |          | Consumption. |           |
|-----------|-------------|----------------|-----------|-----------|----------------|----------|--------------|-----------|
|           | Quantity.   | Value Per Ton. | Value.    | Quantity. | Value Per Ton. | Value.   | Quantity.    | Value.    |
| 1897..... | 26,480      | \$4.00         | \$105,720 | 2,018     | \$7.14         | \$14,401 | 28,448       | \$120,121 |
| 1898..... | 28,247      | 4.00           | 112,988   | 1,914     | 5.83           | 11,356   | 30,161       | 124,344   |
| 1899..... | 32,636      | 4.20           | 137,071   | 4,312     | 6.59           | 28,407   | 36,948       | 165,473   |
| 1900..... | 41,466      | 3.90           | 161,717   | 5,625     | 5.77           | 32,461   | 47,091       | 194,178   |
| 1901..... | 49,070      | 3.22           | 157,844   | 5,004     | 7.04           | 39,442   | 54,674       | 197,286   |

### PRODUCTION OF BARYTES IN THE PRINCIPAL COUNTRIES. (a) (IN METRIC TONS.)

| Year.    | Belgium. | Canada. | France. | Germany. |          |              |         | United Kingdom. | United States. |

(a) From official reports of the respective countries, except the statistics for the United States. (b) Not reported. (c) Output of the mining districts of Clausthal and Bonn. (h) Statistics not yet available.

**Missouri.**—The largest individual production of barytes by States during 1901 was derived from Missouri, where the mines, principally in Washington County, are of very great extent. The great bulk of the shipments is made from Mineral Point, Cadet and Potosi, via the St. Louis, Iron Mountain & Southern Railway.

**Tennessee.**—(By C. S. Herzig.)—The barytes deposits of East Tennessee may be divided into veins and boulders, the former occurring along the Western North Carolina branch of the Southern Railway, around the State line, both east of it in North Carolina and west of it in Tennessee, and the latter around

Sweetwater, about 40 miles west of Knoxville. The strike of both deposits is east of north. The veins occur usually with a quartzite hanging wall and sometimes with a quartzite foot-wall, generally accompanied by a low-grade clayey iron oxide locally called umber, which underlies and at times surrounds the ore itself, making the mining cheap and the ore easily obtained, so that an 8-in. to 10-in. seam of barytes can be worked at a profit. These veins are from 6 to 8 ft. wide and of considerable length; usually the width of the workable veins is from 2 to 4 ft. Due to line of fracture the ore bodies break out in irregular conchoidal blocks. In mining the underlying umber is removed and the ore broken down by hand picks in lumps of from 25 to 100 lb. weight. The barytes is separated from the refuse material, removed to the surface, where it is stacked and dried, and again cleaned before shipment. The principal vein mines, near Myers and Wolf Creek, Tenn., and at Hot Springs, N. C., are owned or controlled for the most part by John T. Williams & Sons, of Knoxville. This concern is building a large mill to grind the ore and manufacture the commercial products.

The boulder deposits at Sweetwater have been operated for many years with indifferent financial success. Large quantities of barytes occur in the residual clay which has resulted from the weathering of the calcareous formation prevailing in that portion of Tennessee. These deposits have a general direction east of north, and in most cases the ore crops out at the surface. The exploitation of these deposits has so far been confined to shallow surface workings, but further development will doubtless show that the ore now found in boulder form embedded in the clay is derived from veins similar to those found near the North Carolina line. It appears that the veins occurred originally in the limestone and due to weathering action, the soluble portions of the limestone were dissolved and washed away, leaving the barytes in its original form and the insoluble iron oxides to color the residual clay. The ore zone is often several hundred feet wide, so that some of the lumps must have been moved a considerable distance from the place where they were originally broken down. The character of the lumps, which vary in size and weight up to 100 lb., is identical with the material mined in the vein deposits. The barytes is usually of good grade, although a small amount of impure ferruginous material is found. The boulder deposits have been mined in a primitive manner by shallow surface pits that have been abandoned as soon as the excavation became too deep for the easy removal of the material. On account of the crudity of the work the cost has been greater than the return. The application of proper mining principles and the control of a mill to convert the crude material into the finished product are two factors which will aid to place operations on a profitable basis. The production of barytes in Tennessee during 1901 was probably less than 15,000 long tons, 70% of which was obtained from the Sweetwater district.

The Hiawassee Mining Co., of Knoxville, which operated extensively in 1900, was declared insolvent during 1901 and was placed in receivers' hands.

The price of crystalline ore of the eastern part of the State varied from \$4.50 to \$4 per ton, according to quality, while the flake variety from the Sweetwater district brought \$3.50 per ton, all f. o. b. cars.

*Virginia.*—The Tri-State Mining Co., of Pittsburg, Pa., is completing a 50-ton plant at Richlands, Tazewell County, to grind the barytes from its mines. The firm of Dingee & Weinman, of Lynchburg, Va., one of the largest operators in the South, has been succeeded by Mephram & Krause Co. At Evington, the Hewitt mines, one of the oldest operative mines in the States, continued its shipment of barytes to Lynchburg.

*Market.*—Consumption in 1901 was good and prices ruled steady. New sellers of the domestic product have appeared, causing closer competition, with the result that some of the larger Virginia and Missouri mines are planning a consolidation which is likely to materialize early in 1902. New York quotations were: Crude, No. 1 domestic, \$9 per short ton; No. 2, \$8; No. 3, \$7.75; for wholesale quantities. German barytes, gray in color, were \$14.50 per ton, and white, \$17.50. Blanc fixe (artificial barium sulphate) was in good request, selling at 1@2c. per pound, according to quantity and quality.

#### TECHNOLOGY.

*Barium Oxide.*—The Bradley & Jacobs process (German Patent No. 111,667, December 16, 1898) for the preparation of barium oxide in the electric furnace, which is operated at Niagara Falls, N. Y., by the United Barium Co., consists in treating an intimate mixture of 137 parts of pure barytes and from 7 to 12 parts carbon in the electric furnace, which transforms the barium sulphate into barium sulphide according to the reaction:  $4\text{BaSO}_4 + 4\text{C} = \text{BaS} + 4\text{CO} + 3\text{BaSO}_4$ . At the high temperature of the electric furnace, barium has a greater affinity for oxygen than for sulphur. A second reaction takes place in which the barium sulphide reduces the sulphate not yet decomposed and forms barium oxide and sulphur dioxide gas as follows:  $3\text{BaSO}_4 + \text{BaS} = 4\text{BaO} + 4\text{SO}_2$ . These reactions are not independent, but occur simultaneously, and as the reduction due to the carbon is much more rapid than that caused by the action of the sulphide there is always an excess of barium sulphide. In practice about 60% barium oxide and about 40% barium sulphate are obtained, the residual undecomposed sulphate amounting to less than 1%. The addition of barytes when the reaction has been under way for some time aids in the production of barium oxide. The resultant mixture is treated with hot water and barium hydrate obtained; which can be subsequently crystallized as  $\text{BaOH}_2 \cdot 8\text{H}_2\text{O}$  from the concentrated solution. The furnaces employed are operated continuously and have a maximum power consumption of 500 K.W. and a maximum output of 8 tons of product per 24 hours. The crystals of barium hydrate containing less than 1% impurity, after a thorough washing with cold water and drying, are melted and run into thin iron drums of 500 lb. capacity. The efficiency of this process extracts from 97 to 98% of the barium sulphate in the crude mineral and at the relatively low cost of treatment it can produce barium salts at a price which will doubtless result in a great increase in their consumption. Although in operation less than a year, the capacity of the plant has been increased to 60 tons per day. Hitherto barium hydrate has been consumed chiefly by the beet sugar industry to remove the sugar from molasses. Steps are being taken to utilize, for the manufacture

of sulphuric acid, the sulphurous gas which is evolved during the smelting of barytes, which would make the process well rounded.

*Barium Dioxide.*—The production of hydrogen dioxide from barium dioxide in France during 1899 amounted to 5,800 tons, which was used to manufacture oxygenated water; 11 works in France are engaged in the manufacture of oxygenated water, 4 of these making the barium peroxide as well. Oxygenated water is used extensively in bleaching linen, silk, straw, feathers, coral ivory. It is also used as an antiseptic and as a cosmetic in bleaching the hair. The present world's production of barium dioxide is estimated at 10,000 long tons annually.

*Lithophone.*—This valuable pigment consists essentially of a mixture of barytes with zinc oxide and zinc sulphate in varying proportions. The best quality contains from 65 to 70%  $\text{BaSO}_4$ , 12 to 15%  $\text{ZnS}$  and 10 to 13%  $\text{ZnO}$ . Details of the manufacture of lithophone are given under the caption "Zinc and Cadmium," later on in this volume.

*Review of Analytical Chemistry.*—(By Edmund H. Miller.)—C. H. Peters<sup>1</sup> investigated the precipitation of barium, strontium, and calcium as oxalates, and their subsequent determination by indirect titration with potassium permanganate. In order to get sufficiently complete precipitation of strontium oxalate, the volume of the solution should be 100 c.c., and should contain one-fifth 85% alcohol, as this oxalate is soluble in 12,000 parts of water. For barium oxalate, which is soluble in 2,590 parts of water, one-third of the solution should be alcohol. The conditions for precipitation are as follows: To the barium solution 100 c.c. in volume and containing about 30% alcohol, add an excess of ammonium oxalate and allow to stand over night; filter on asbestos in a Gooch crucible, wash with water containing 30% alcohol and dry over a flame to expel the alcohol, which would reduce permanganate. The crucible with the precipitate is put in a large beaker, with from 100 to 200 c.c. of water, from 5 to 10 c.c. concentrated hydrochloric acid, and from 0.5 to 1 g. of manganous chloride, and the resulting solution titrated by permanganate at a temperature of from 35 to 40°C. The results given are quite satisfactory, and better than when sulphuric acid is used, as the barium sulphate retains oxalic acid by occlusion. In regard to the precipitation of these oxalates when used as a means of separation from magnesium, the recent article by Prof. Richards<sup>2</sup> affords very valuable information.

E. Groschuff<sup>3</sup> gives the solubility of the different hydrates of barium oxalate and also of the acid oxalate  $\text{BaC}_2\text{O}_4 \cdot \text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$ .

D. Vitali<sup>4</sup> describes a method for the recognition of barium compounds in the contents of the stomach to be used in cases of poisoning.

L. Dobbin<sup>5</sup> calls attention to the very considerable solubility of barium sulphate in solutions of sodium thiosulphate ("hypo"), and suggests this as another source of error in the difficult determination of mixtures of sulphates, sulphites, thiosulphates, etc.

## BISMUTH.

THE supply of bismuth ores in the United States continues to be obtained from Colorado, and in 1901 the production amounted to 318·6 short tons, as compared with 220 short tons in 1900. Lake County contributed 253·6 short tons of ore of from 4 to 10% Bi, while Ouray County produced 65 short tons of ore, which varied from 6 to 12% bismuth content. The ore contained gold and silver, for which the producers were paid. The price paid for bismuth ranged from \$2 to \$11 per unit. Owing to the limited demand for the metal the producers of ore are disinclined to report their production and the details of market conditions. As nearly as can be ascertained the output of 318·6 short tons was valued at \$25,488, less transportation and treatment charges, or an average of \$80 per ton. In recent years practically the entire output was purchased by the Leadville Sampler, at Leadville, the State Ore Sampling Works, at Denver, or was shipped direct to Johnson, Matthey & Co., Ltd., England. During 1901, however, a considerable portion was diverted to other buyers.

The world's supply of metallic bismuth is controlled by the combined interests of Johnson, Matthey & Co., Ltd., and the Saxon Government, who regulate absolutely the production and prices of the metal and its ores. The supply of this metal greatly exceeds the demand and necessitated a combination of interests in order to maintain the price at a figure which would be remunerative to mine owners. The schedule of prices for ore during 1901 showed no change from the previous year. The price is based on the market price of metal, and with the latter at \$1·25 a lb. the following rates were paid on delivery at the smelting works, all deductions for treatment having been made: 10% ore, \$150 per ton; 15% ore, \$200 per ton; 20% ore, \$350 per ton; 30% ore, \$550 per ton; 40% ore, \$750 per ton, 50% ore, \$1,000 per ton.

The price for refined metallic bismuth ranged from \$2·25 per lb. in January-March to \$2·05 in April-June; \$2·025 in July and August; \$1·64 in September to the closing quotation of \$1·50 in October-December. The drop in price was due to the purchase of ore by buyers outside of the so-called "Bismuth Association."

While bismuth occurs both in the combined and free state in many of the Western States the mining of its ores is limited to Colorado. The principal

minerals in the State are: the carbonate, which occurs in Lake, Larimer, Boulder and Chaffee counties; native bismuth in Summit, Jefferson, Boulder and Larimer counties; tellurate and telluride in Boulder and Ouray counties; sulphobismuthite in Park, Custer, Ouray, Hinsdale, Clear Creek, La Plata, Boulder, San Juan and Lake counties.

The importation of bismuth ore in the United States was 165,182 lb. valued at \$239,906, against 180,433 lb. valued at \$246,597, in 1900. In addition to this there was a small importation of bismuth compounds in medicinal preparations.

*Review of Analytical Chemistry.*—(By Edmund H. Miller.)—Three new methods for the estimation of bismuth have appeared during the past year:—

(1) Warwick and Kyle<sup>1</sup> describe, with a few additional details Patterson Muir's method, as given by Sutton,<sup>2</sup> of which the following is an abstract: 1 g. of finely ground ore is treated with from 5 to 10 c.c. of concentrated nitric acid, and evaporated to dryness on a hot plate, but not baked; 5 c.c. of nitric acid are added, and the residue broken up; then 25 c.c. of water, and the whole transferred to a beaker and diluted to 100 c.c. with hot water. The insoluble residue is not filtered out, but the bismuth is precipitated in the solution containing 5% nitric acid by an excess (5 g.) of ammonium oxalate or<sup>3</sup> oxalic acid; not potassium oxalate, as used in a later method by Muir and Robb, as it gives an insoluble double salt,  $\text{Bi}_2(\text{C}_2\text{O}_4)_3 \cdot \text{K}_2\text{C}_2\text{O}_4$ : boil vigorously for five minutes; allow to cool and settle; decant the clear solution through a filter, leaving the precipitate in the beaker. The precipitate is boiled with two successive portions of water (about 50 c.c. each), and filtered through the filter already used. This treatment converts the bismuth to a basic oxalate, and is sufficient for ores containing about 10%; if richer, re-treat till the filtrate is neutral (showing that all the oxalic acid is removed, except that combined with the bismuth as a double salt). The precipitate of basic bismuth oxalate is washed down to the point of the funnel and dissolved through into the beaker containing the rest of the precipitate by a little hydrochloric acid (1 to 1), warmed till solution is complete (from 2 to 5 c.c. of hydrochloric acid being required), and diluted to 250 c.c. with hot water; then neutralized by ammonia and reacidified by dilute sulphuric acid. The oxalic acid so liberated is titrated at 70 to 100°C. by standard permanganate as usual. The authors state that as regards permanganate, 10 mg. iron are equivalent to 18.68 mg. of bismuth; this corresponds to one molecule of oxalic acid for each atom of bismuth, as given by Muir. According to this last-named authority, if other metals are present which give insoluble oxalates, the bismuth must be first separated as oxychloride. Warwick and Kyle state that this is unnecessary, and claim that the method is accurate to within about 0.1%, even in the presence of large amounts of copper. This is in direct contradiction to the recent work of Peters<sup>4</sup> on the precipitation of copper by oxalic acid, and to the experience of C. A. Grabill<sup>5</sup> in testing the method. The explanation of this difference of opinion lies

<sup>1</sup> *Engineering and Mining Journal*, April 13, 1901.

<sup>4</sup> *Zeitschrift fuer Anorganische Chemie*, 26, 111, 1901; also, *American Journal of Science*, No. 59; *Chemical News*, 83, May 10, 1901, 221 et seq.

<sup>5</sup> *Engineering and Mining Journal*, Sept. 20, 1901.

partly in the different behavior of ammonium oxalate and of oxalic acid. Copper oxalate is readily soluble in the first, but not in the latter. (Method not recommended.)

(2) G. Frerichs<sup>6</sup> employs the reaction of bismuth sulphide on silver nitrate for the determination of bismuth in surgical dressings, etc. The freshly precipitated sulphide is shaken vigorously with a measured excess of N/10 silver nitrate solution and 10 c.c. of nitric acid, made up to 100 c.c., and the excess of silver in 50 c.c. found by Volhard's method, titration with ammonium sulphocyanide using ferric alum as indicator. The essential reaction is the formation of silver sulphide and bismuth nitrate; 1 c.c. N/10 silver nitrate is equivalent to 0.00693 g. of bismuth.

(3) Karl Wimmenauer,<sup>7</sup> after reviewing and repeating the work already done on the electrolytic deposition of bismuth, gives the following conditions as the most satisfactory for its determination: From 0.1 to 0.3 g. of bismuth nitrate is dissolved in from 2 to 4 c.c. of glycerine solution, one part of glycerine to two parts of water, diluted to 150 c.c. and electrolyzed by a current of 2 volts and 0.1 ampere. The temperature is gradually raised to 50°C. and the current density reduced to 0.05 amperes. When the electrolyte was kept agitated, as much as 0.4 g. of bismuth was deposited as a bright dense deposit in three hours. The results given are very satisfactory, especially when an electrode having a rough surface is used.

Prof. Smith in a recent address before the American Chemical Society stated that bismuth could be deposited quantitatively from a solution containing a small quantity of free sulphuric acid. The full details have not yet been published; but the following method has been used with success in Denver:<sup>8</sup> 0.5 g. of bismuth ore is boiled for 10 minutes with 10 c.c. nitric acid, 10 c.c. of sulphuric acid is added and evaporated to white fumes; then taken up with 50 c.c. of water and boiled, and the residue filtered off, cooled, diluted to 125 c.c., and electrolyzed at the ordinary temperature for four hours. The current used was from 3 to 4 volts and from 0.3 to 0.5 ampere per 100 sq. cm. of cathode area.

## BORAX.

THE production of borax in the United States continues to be derived mainly from the colemanite deposits of California, although the marsh deposits of California, Oregon and Nevada contribute a small quota to the total output, which during 1901 amounted to 17,887 short tons of crude borax, valued at \$314,811, and 5,344 short tons of refined borax, valued at \$697,307, the total value being \$1,012,118. Of the total output California produced 16,887 short tons crude borax, valued at \$297,198, and 5,344 short tons refined borax, valued at \$697,307, the total value of the product from this State being \$994,505.

### IMPORTS OF BORATES, ETC., INTO THE UNITED STATES.

*California.*—The chief items of interest in the crude borax industry during 1901 were the development and largely increased production of the colemanite deposits of Ventura County and the introduction of new methods and new capital in the working of the low-grade mud deposits near Daggett. The Western Mineral Co. has erected a modern plant and has increased its capacity considerably, its product being a boric acid concentrate, which is shipped East for making borax. Several important chemical difficulties, which have heretofore baffled chemists, have been overcome, and the production of boric acid is now being actively developed.

The Standard Sanitary Co., of Pittsburg, Pa., has absorbed the Columbia Mining & Chemical Co., whose great mud deposits near Daggett and extensive plant in the town are now operated by the American Borax Co. New machinery has been added. The air method of making sulphurous acid has replaced the steam method and the capacity of the plant considerably increased. A railroad has recently been built from the mines to the works, a distance of six miles, and

elaborate arrangements have been made to handle cheaply large quantities of low-grade borate ores. The product, a boric acid concentrate, will be mostly used by the company at its works at Pittsburg, Pa., where it consumes large quantities of boric acid. Careful laboratory work is being done by both companies, and it is worthy of note to record that this is the first determined effort made to work low-grade deposits of calcium borate ores in this country.

The Ventura colemanite mine, owned by the Stauffer Chemical Co., yields upward of 100 tons of high-grade calcium borate per month for manufacture into boric acid at the factories of the company in San Francisco. Considerable development work has been done during the year on this very promising property.

No new borate ore bodies have been discovered of late. The marshes in Nevada and California have been worked to some extent, but the output therefrom is comparatively insignificant in the market.

The Pacific Coast Borax Co., as heretofore, supplies nearly all the borax used in this country and a proportion of the boric acid as well. Its colemanite mines at Borate, 12 miles northeast of Daggett, continue to yield as much ore as the market requires, though the greater depth of mining has increased the cost of extraction. This company controls the borax market in the United States, and has shown wise conservatism in resisting the temptation to increase prices during the recent period of high values. The burning of its large factory at Bayonne, N. J., in April, 1902, has had no effect upon the market, nor even compelled the reopening of the plant at Alameda, Cal. There is no immediate prospect of any decided increase in the production of borate nor change of values.

*Oregon.*—The marsh deposits of sodium borate in Harvey County have been operated for the past five years and the refineries have produced a yearly output of 400 short tons of refined borax, which is carried by mules to Winnemucca, on the Central Pacific Railway, and thence to Chicago, St. Louis, and occasionally to San Francisco. The deposit extends over 10,000 acres south of Lake Alvord, and with the existing transportation facilities not more than 25% of the area can yield ore of sufficient richness to pay for working. The Rose Valley Borax Co. owns 2,000 acres of the richest portion of the deposit close to the lake. The ground is level and treeless and is incrustated with a layer of sodium borate several inches thick, which contains also sodium carbonate, sodium sulphate, sodium chloride, and other salts in varying proportions. During the long dry summers, the loose surface deposit is shoveled into small heaps and is replaced with a second incrustation within a comparatively short time. No mining is done in winter, and sufficient material is collected in the summer months to furnish the supply to the refining works so that they may operate throughout the entire year. The crude material, containing from 5 to 20% boric acid, is shoveled into tanks filled with boiling water, to which is added chlorine or sulphuric acid to dissolve the alkali salts and free the boric acid. After 24 hours the clear supernatant liquor is drawn off into crystallizing tanks and allowed to cool, forming white pearly scales of high-grade boric acid and a mother liquor which is used repeatedly until it contains a sufficient quantity of sodium salts to warrant a separate treatment.

*Market.*—There has been but little fluctuation in the price of borax during 1901, the price being from 7 to 7.25c. for the refined article and 6.75 to 7c.

for the concentrated product. The concentrated grade, however, is not of uniform quality and is gradually disappearing from the market.

(a) From official reports of the respective countries except the United States. (b) Exports. (c) Fiscal years. (d) Product of refined borax. The manufacture of boric acid was begun in the United States in 1890, in which year there was a production of 621,000 lb. There are no statistics for subsequent years. (h) Not reported.

The Borax Consolidated, Ltd., gives a very favorable report for the fiscal year ending September 30, 1901. Net profits for the year were £190,278, from which interim dividends of £22,000 on preferred stock and £30,000 on ordinary stock—£52,000 in all—were paid, leaving £138,278. Adding £13,360 brought forward from previous year, gives a total surplus of £151,638. The mines and deposits continue to yield satisfactory returns, and as a result of the systematic development work a vast quantity of high-grade borate has been blocked out.

*Argentina.*—The International Borax Co. during 1901 operated the Tres Moros mines; some 500 laborers were employed, and they mined on an average 700 tons per month. The shipments from the Province of Salta to Europe in 1901 exceeded 16,000 tons.

*Chile.*—Borax and boracite are found principally in the districts of Ascotan and Carcota, Province of Antofagasta, and in the Department of Copiapo, Province of Atacama. The deposits of Ascotan and Carcota were worked for a long time by a Chilean company and are now owned by a California concern. In 1900 these mines produced 13,176 metric tons calcined boracite and 26 metric tons borax. A syndicate has recently purchased a borax property known as the Barateras de San Juan de Diologue, at a stated price of \$150,000.

*Russia.*—Borax is found on the Kertch and Taman peninsulas of southern Russia, where it occurs in connection with mud volcanoes. The mud soon after eruption is encrusted with various salts including borax, soda and salt, which are recovered by dissolving in water and evaporation.

*Technology of Borax Manufacture.*—The mineral borocalcite, a calcium borate, from Asia Minor furnishes a base for the manufacture of the greater part of the borax consumed in Europe. The crude mineral is treated with caustic soda, which forms borax and calcium carbonate. The best results were obtained by the use of a mixture of caustic soda and sodium bicarbonate; the ore is finely crushed in a mill and 15 parts mineral are placed in a steam-heated boiler with 60 parts water, 8 parts sodium bicarbonate, and 2 parts caustic soda; the whole is boiled for about three hours. The resultant mass is filtered and the hot filtrate crystallized, yields at the end of a few days crystals of borax, which are steam dried. The crystals thus obtained are assorted and barrelled. The cake of calcium carbonate remaining in the filter-press is washed with water until the borax is completely extracted, and is then sold to glass, paper or cement works. It is esti-

mated that 100 lb. of borocalcite will yield from 100 to 105 lb. of crystallized borax.

*Review of Analytical Chemistry.*—(By Edmund H. Miller.)—E. Polenske<sup>1</sup> states that when borax is distilled with methyl alcohol, from 57 to 59% of the boric acid present passes over in the distillate, about 50% readily, the remainder slowly. Sodium metaborate,  $\text{Na}_2\text{B}_2\text{O}_4$ , in distillation with methyl alcohol gives off boric acid till the composition becomes  $5\text{Na}_2\text{O}, 4\text{B}_2\text{O}_3$ , when the excess of soda prevents the formation of boric esters.

Luhrig<sup>2</sup> confirms the accuracy of the titration method based on the fact that boric acid in the presence of glycerine does not react acid with methyl orange, but does with phenolphthalëin and can be titrated by alkali using this indicator. Jorgensen's directions were followed. This method is applied to borax by liberating the boric acid by an excess of sulphuric acid then neutralizing this excess by caustic soda, using methyl orange, which leaves the boric acid free, glycerine and phenolphthalëin are then added, and the boric acid titrated by standard sodium hydroxide.

E. Zschimmer<sup>3</sup> gives the following directions for the analysis of Italian crude boric acid:—

(1) One grain of the air-dried sample is dissolved in 300 c.c. of glycerine and water and titrated with standard barium hydroxide, using phenolphthalëin as indicator; when the pink color appears more glycerine is added, and if not permanent the titration is continued.

(2) The sulphur trioxide is estimated as usual in 1 g. of sample.

(3) Several mixtures of boric acid and ammonium sulphate of known composition are made and titrated so as to find the number of c.c. which actually correspond to 1 gm. of sulphur trioxide present as ammonium sulphate.

(4) The glycerine is tested for acidity. From the volume of barium hydroxide used, deduct that required for the sulphur trioxide found to be present and calculate the remainder of boric acid.

Carnielli,<sup>4</sup> after comparing a number of methods for boric acid, gives the preference to Thompson's volumetric method (already described), and mentions favorably the distillation method of Gooch-Rosenblatt. An extensive review of the methods for the determination of boric acid will be found in *Zeitschrift fuer Analytische Chemie*, Vol. XXXIX., p. 465, 1900.

## BROMINE.

THE production of bromine in the United States during 1901, including the quantity of bromine contained in potassium bromide, amounted to 552,043 lb., as compared with 521,444 lb. in 1900. The production of bromine in the world continued to be controlled by the associated American producers and by the Leopoldshall-Stassfurt convention, which has several years longer to run.

*Michigan.*—The production of bromine in potassium bromide during 1901 was equivalent to 163,120 lb., which, with the 54,875 lb. of liquid bromine produced, gives an aggregate of 217,995 lb. The Midland companies still control the bromine situation in the United States, although a small quantity has been made *sub rosa* from the Saginaw bitters. The Red Cross well at Big Rapids is being fitted up to produce bromine commercially, and a shaft is being sunk for rock salt just south of Detroit. The deposit is large and offers a good field.

## CALCIUM CARBIDE AND ACETYLENE.

THE progress of the calcium carbide industry depends to a large extent upon the new uses for acetylene gas as well as upon its normal established consumption for industrial purposes. The possessor of a quantity of carbide cannot use it until he has the necessary appliances to convert it into acetylene gas. In spite of their mutual interdependence the manufacture and sale of acetylene apparatus is not necessarily connected with the carbide industry, and in fact, the two industries are operated separately and with separate capital throughout the world.

Toward the end of the year 1901, the acetylene industry showed signs of healthful progress. The apparent ease of bringing calcium carbide and water into contact, and the obvious multiplicity of devices, with which it is possible to accomplish this end, have unfortunately, from the very beginning attracted the attention of those who have possessed but a fair mechanical knowledge, and have not at all understood the chemistry involved in the combustion of inflammable gases. Owing to the small cost of constructing an apparatus, or so-called "generator," in which carbide and water are brought into contact, the field has been attractive to incompetent inventors, with the result that poorly designed and badly constructed machines have been largely introduced. Many instances of dissatisfaction with the use of acetylene gas are recorded which have been due to the annoyances and danger caused by the use of inferior apparatus, but the excellence of the light, *per se*, has fortunately led to the conclusion that the fault lay with the details of the apparatus and not with the gas itself.

Carbon and hydrogen combine to form an almost infinite number of substances in which more hydrogen atoms than atoms of carbon are almost invariably contained. The lowest in the series is acetylene  $C_2H_2$ , possessing not only the highest calorific power of all, but also the greatest illuminating power. Without reviewing the chemistry of the manufacture of acetylene, which has already been fully described in previous volumes of THE MINERAL INDUSTRY, the following table of the illuminating power of various hydrocarbons of the  $C_nH_x$  series is of interest:—

| Name.        | Formula. | Candle Power. | Name.          | Formula. | Candle Power. |
|--------------|----------|---------------|----------------|----------|---------------|
| Methane..... | $CH_4$   | 5.2           | Ethylene.....  | $C_2H_4$ | 70.0          |
| Ethane.....  | $C_2H_6$ | 37.7          | Butylene.....  | $C_4H_8$ | 133.0         |
| Propane..... | $C_3H_8$ | 56.7          | Acetylene..... | $C_2H_2$ | 240.0         |

In the light of our present knowledge it is impossible to form compounds of a lower ratio of carbon and hydrogen than that existing in acetylene,  $C_2H_2$ , and while there are many substances of the same numerical atomic ratio, they have an increased number of atoms to the molecule, as for example, benzene,  $C_6H_6$ . It is found that the greater number of atoms present the smaller the illuminating power; thus acetylene,  $C_2H_2$ , has a candle power of 240, while that for benzene,  $C_6H_6$ , is 126; continuing the series, many oils of lesser candle power are obtained, reaching finally a brown oil of indeterminate absolute composition which is practically incombustible.

*Acetylene Generators.*—The design and construction of acetylene generators, particularly in the United States, has shown a marked improvement in the past few years, a result due in part to the competition among manufacturers, partly to the increasing knowledge of the requirements of the industry among buyers, and in large measure to the insurance interests of the country. Within the past three years the fire insurance companies in the United States, through the National Board of Fire Underwriters, have organized a laboratory at 67 E. 21st Street, Chicago, Ill., at present in charge of Mr. W. H. Merrill, for the examination of all fire hazards and fire prevention devices, which naturally includes acetylene apparatus. Acetylene generators constructed in accordance with the rules of the committee, and upon passing prescribed tests, are placed upon the so-called "List of Permitted Machines," which placement is in most cases followed by the consent of the insurance companies to the installation of that apparatus within insured premises with no addition to the rate of insurance.

During 1901 the Engineers' Committee of the Board increased the requirements relating to acetylene apparatus and a systematic re-examination of previously permitted machines was vigorously enforced, which resulted in the removal from the "permitted list" of 79 machines. This, with the addition of 34 new ones, brought the net total on the list at the close of the year to 100. Late in 1901 a standard for the examination of acetylene table lamps and other portable apparatus was adopted by the Engineers' Committee, under which an acetylene lamp to be placed upon the permitted list must be practically free from fire hazard. One table lamp was placed upon the permitted list, and its rapid introduction was promptly begun by the manufacturer, as a pronounced demand has always existed for a lamp of this character.

The United States Post Office granted during the year 129 patents for acetylene apparatus, making a total of 959 patents in this class.

In Europe the manufacturers of acetylene generators have confined themselves almost exclusively to machines of the non-automatic type, in most of which enough carbide is fed into the water in the machine, by hand, to generate a sufficient supply of gas to last during the daily lighting hours. This plan requires the use of a holder of sufficient capacity to contain gas for a maximum requirement of 24 hours. Generators of this type, however, are not installed in the buildings to be lighted. Automatic generators in Europe are comparatively crude, and none are sufficiently well designed or constructed to pass the requirements of the insurance interests of the United States. Usually automatic machines require some extraneous source of power for the operation of the feeding mechanism,

which complicates the operation. It is noted that most generators are equipped with chemical purifiers to remove impurities from the acetylene produced from carbide manufactured in Europe, while in America purifiers are not used, a distinction probably due to the difference in the purity of the raw material procurable in the two countries for the manufacture of carbide.

*Lamps.*—In England and Germany many portable acetylene lamps are manufactured, particularly for automobiles, carriages and bicycles, although a portable lamp for indoor use has not yet been marketed. In America, the passing of the general use of the bicycle, has greatly diminished the use of acetylene in portable lamps; but the introduction of table lamps and apparatus for automobile and carriage lighting, bids fair to take the place of the large consumption previously absorbed by bicycle lamps.

*Car Lighting.*—During the year the use of acetylene for lighting railroad passenger cars has greatly increased throughout Europe and America, and experiments were conducted in coach or in engine lighting by many railroads in the United States. In Germany, where the greatest quantity of acetylene is used for coach lighting, the Government railroads use it as an enricher for gas of low candle power, the resultant mixed gas containing about 25% acetylene and 75% of a gas made from shale. It is estimated that 5,500 tons of calcium carbide is consumed annually in Germany for making acetylene for car lighting purposes. In German practice the mixed gases are compressed in storage tanks under the cars at about 150 lb. per sq. in. The gas is handled and utilized in a similar manner to the Pintsch oil-gas for lighting cars.

In the United States most of the experimenting with acetylene car lighting has been confined to the use of automatic generators located within the car to be lighted. Four separate concerns are exploiting this system of car lighting in the United States, one of which has introduced generating and compressing plants for the lighting of cars with acetylene from central stations, using storage tanks on the cars for the compressed gas. Apart from Germany there has been little commercial progress made in the use of acetylene for car lighting in Europe.

The Great Northern Railroad in the United States has 75 passenger coaches lighted by this gas, and 80 additional cars are being equipped with the apparatus. The system in use consists of compressing acetylene to 150 lb. per sq. in., storing the compressed gas in tanks under the cars, and providing against accidents from dissociation in case of fire by the use of connections which fuse at a low temperature.

*Acetone.*—The use of acetone<sup>1</sup> as an absorbent in connection with acetylene has received much attention during the year, particularly for car lighting, and several coaches on a prominent railroad in the United States are lighted experimentally by this method. By using a storage tank filled with acetone, the volume of acetylene which can be stored therein is increased once for each pound pressure. Excellent results were obtained by placing the acetone in storage tanks filled with

<sup>1</sup> Acetone is a colorless mobile liquid which boils at 56.3°C., mixes with water in all proportions, and is an excellent solvent for the gases of the hydrocarbon series. It may be produced commercially according to the Squibb method by passing acetic acid vapor through a rotating iron cylinder, heated to 500° to 600°C., which contains pumice stone and precipitated barium carbonate. A cruder method of production is from the dry distillation of calcium acetate.

porous brick to facilitate the absorption. An additional advantage is claimed for the porous brick, in that dissociation is localized in the event of its occurrence. While the method of storing acetylene in acetone was developed in France, its commercial development has made but little progress in that country.

*Power and Fuel Purposes.*—The use of acetylene for power or other fuel purposes has made but little progress and it is improbable that the general use of acetylene in this field will advance, unless for some special power purpose, as an automobile motor. Notwithstanding the economy in the use of acetylene as an illuminant, it cannot be used economically as a fuel, for its heating value is not in proportion to the cost per 1,000 cu. ft. or other unit of value of other fuels.

*Central Plants for Illumination.*—During 1901 small municipalities and local capital have investigated the feasibility of supplying acetylene from centrally situated plants to consumers located within reasonable distances. In France the introduction of these plants has made rapid progress. Forty central plants are reported in operation in that country of which 15 are constructed on the Turrs system for the distribution of gas. This system provides for the distribution of the gas through 0.5-in. to 2-in. lead pipes with wiped joints, with the gas compressed to about 0.5 lb. per sq. in., an unusually high pressure, but one that is necessary on account of the small size of the pipes. It is claimed that the cost of lead-pipe construction does not exceed the cost for wrought or cast-iron gas mains, and the very important element of leakage is eliminated. The Turrs plants are erected and operated by a private corporation which is reported to have been very successful.

There are 36 town-lighting plants in operation in Germany, and six in England, while in America 40 plants are in operation or under construction. These figures do not include a few large plants which furnish acetylene to groups of buildings, but which cannot fairly be designated as town-lighting plants.

The use of acetylene throughout the world is confined to illumination, its use for chemical or other purposes being practically negligible. Probably 65% of the world's consumption of acetylene is in individual plants for lighting single buildings, most of which are located beyond the reach of gas or electric companies selling illumination even at the low figures prevailing in the large cities.

*Publications.*—A number of periodicals devoted exclusively to the acetylene industry are published regularly, three in Germany, two in France, two in England, and one in the United States. In addition many trade papers devote considerable space to this important industry.

*Exhibits.*—At the Pan-American Exposition at Buffalo, N. Y., was an elaborate exhibition and display of acetylene and its appliances. The acetylene building was specially constructed and illuminated with 5,000 jets, many being on the exterior. The educational advantages of this display of acetylene apparatus have since been felt by the industry. In addition to the acetylene building, others in the Exposition were lighted by acetylene, principally the large railroad station and the transportation building. The central plant supplying all buildings had a daily output of 10,000 cu. ft., and at that time was the largest acetylene installation in the world.

The annual meeting of the International Acetylene Association was held at

Buffalo, June 20 and 21, 1901, within the grounds of the Pan-American Exposition, and the complete proceedings, including all papers read, were published as a supplement to *The Acetylene Gas Journal*.

*Calcium Carbide*.—During 1901 practically no increase was made to the world's calcium carbide manufacture. In previous years the demand was so far anticipated that even at the close of 1901 the manufacturing capacity was at least four times greater than the market requirements. This condition of over production was universal, with the possible exception of Great Britain, and was most noticeable in countries where private ownership of patents did not restrict the erection of plants. The extraordinary rate at which plants for manufacturing this product were erected may be attributed to several causes, chief among which are (1) a spasmodic demand, making it utterly impossible to judge future requirements, (2) a universal belief that the profit in manufacturing this product is very large, (3) the activity of manufacturers of electrical apparatus seeking a market for their goods but without direct interest in the permanency of the carbide business, (4) a general lack of appreciation of the fact that the demand for carbide is dependent primarily upon the progress of the business of introducing acetylene apparatus for illuminating purposes.

On the European continent, allowing a reasonable rate of increase in the consumption of acetylene, it will probably require 10 years before the demand for calcium carbide equals the present manufacturing capacity. It is evident as well that without improved processes the present plants will not meet future trade requirements.

Plants for the manufacture of calcium carbide are located in the principal countries as follows: Germany, 7; Austria, 8; Spain, 2; Italy, 4; Norway, 3; Sweden, 4; Switzerland, 13; France, 21; Finland, 2; Russia, 2; England, 2; United States, 2; Canada, 2; Argentine Republic, 1; total, 73; and in the aggregate 254,350 H.P. is installed for the manufacture of this product, of which, however, but 63,900 H.P. is in use at present.

The association of calcium carbide manufacturers in Germany, Switzerland, Austria and Sweden, formed late in 1900, with central sales office at Frankfort, has been disbanded, but a second attempt is now being made to regulate the production of carbide in Germany.

*Markets*.—During 1901 a decided increase in the selling price of calcium carbide was made on the European continent, due to the formation of a syndicate of manufacturers which was organized for the purpose of limiting production and maintaining prices, a plan necessary on account of previous competition and ruinous prices. The syndicate is said to include all the manufacturers in Europe except those in Great Britain and Italy. Previous attempts to maintain similar arrangements in the same territory failed for lack of complete co-operation. The realization of the absolute necessity for maintaining prices and the apportionment of the actual demand, bids fair to maintain the present combination. The selling prices to dealers of the Continent, established at the time of the formation of the syndicate, were about \$71.50 per ton, including packages, f. o. b. several distributing points. Owing to competition, this price was quickly reduced to about \$64.25 per ton, where it will probably remain.

In the United States a radical change in method of distribution was adopted, which resulted in a uniform price for carbide over practically all the section east of the Rocky Mountains. This was accomplished by the establishment of warehouses at all important centers which supplied carbide at \$70 per ton including packages, f. o. b. cars at each of the distributing points. As a result large reductions were made in the cost to consumers, amounting in some sections to nearly \$25 per ton.

*Tariff.*—The United States exacts an ad valorem duty of 25% upon importation of calcium carbide; Canada, 25%, while Germany, Belgium, Greece, Netherlands, and Norway admit it free. The following ad valorem duties are assessed on production: Bulgaria, 14%; Denmark, 10%; France, 5%; Sweden, 15%; Italy exacts a specific duty of \$21.80 per ton and Switzerland, \$14.52.

*Transportation.*—In Europe, while there are no special regulations by the transportation companies as to the package in which calcium carbide shall be shipped, the material is nevertheless considered hazardous and freight rates are levied accordingly. The railroad companies in the United States specify weight and construction of packages, and classify the material so that reasonable freight rates prevail.

*Furnace Practice.*—In Europe the prevailing custom is to remove calcium carbide from the furnaces by the so-called "tapping" process, while in America the ingots are taken directly from the furnace. It is now conceded that a more uniform quality can be produced by the latter method, and the greater purity of the raw materials in America yields a higher grade of calcium carbide than that generally produced in Europe.

*Sizes of Carbide.*—Various devices for generating acetylene gas have required the carbide to be crushed and screened to different sizes in order to insure a satisfactory operation of the apparatus. The manufacturers in Great Britain furnish nine sizes varying from pieces 0.5 in. to 5 in. in size. Germany has three commercial sizes; Austria, four; America four, and Canada four. The smaller sizes produce proportionately less gas than the larger ones, due to the losses in acetylene owing to increased aggregate surface exposed during packing and handling. Because of the comparative ease of construction of a mechanism to feed the smaller sizes of carbide automatically, it is noted that the generator manufacturers are inclined to construct generators on this plan. This sacrifice of efficiency, however, is leading to the manufacture of apparatus which will handle the larger sizes successfully.

*Quality of Carbide.*—The manufacturers in Great Britain and in the United States guarantee a yield of 5 cu. ft. of acetylene gas per pound of the larger size carbide. In France there is no guarantee or legal regulations, and the quality is said to vary from about 4.75 cu. ft. of gas per pound to 3.70 cu. ft., the general average being probably 4.34 cu. ft.

In Europe the standard of quality is 4.81 cu. ft. of gas per pound of carbide, though in many cases the yield is below that figure and an allowance is made accordingly.

In Germany rules have been adopted which provide that the average yield from a given package shall be 4.65 cu. ft. of gas per pound at 15°C. and at 29.92 in.

barometric pressure, 2% variation from the standard being allowed. The buyer is obliged to accept carbide yielding as low as 4.25 cu. ft. of gas, although a proportionate allowance is made. Material yielding under 4.25 cu. ft. per pound need not be accepted. Specific means for taking samples and making tests are provided.

A broad view of the carbide and acetylene industries indicates a steady and healthful growth upon legitimate lines and at only fair manufacturers' profits. Most of the false impressions concerning the possibilities of the business have been corrected, and the losses which have been sustained will probably deter overproduction and ruinous competition in the future.

## CARBORUNDUM.

THE carborundum industry during 1901 continued to show great progress, and the sole manufacturer using two units of 1,000 H.P. each, produced 3,838,175 lb. of crude carborundum, valued at \$345,435, as compared with 1,741,245 lb., valued at \$216,090 in 1900. Of the production in 1901, 1,414,694 lb. was used in the company's factory for the manufacture of wheels, paper, cloth, etc.; 487,682 lb. was sold in the form of grains and powders for abrasive purposes; and 1,693,774 lb. was disposed of to steel makers for use as a substitute for ferro-silicon. A very conservative estimate of the relative values of carborundum and emery for abrasive purposes makes 1 lb. of the former equivalent to 3 lb. of the latter and from this it follows that carborundum as an abrasive replaced, last year, about 5,700,000 lb. of emery. Assuming that ferro-silicon averages 15% Si, 4 lb. of that material is replaced by 1 lb. of carborundum, so that the carborundum produced in 1901 replaced about 6,800,000 lb. of ferro-silicon.

The consumption of carborundum is increasing so rapidly that preparations are being made to install an additional 1,000-H.P. unit in the factory at Niagara Falls, an increase which will give a total annual production of approximately 5,800,000 lb. of carborundum.

It is interesting to note that in the original patent for carborundum, stress was laid on its great "refractability and infusibility"—two valuable properties, the practical value of which is now beginning to be recognized.

## CEMENT.

THE production of Portland cement in the United States during 1901 exceeded that of the previous year by 4,719,586 bbl., the increase coming almost entirely from the Portland cement mills of Pennsylvania, New Jersey and Michigan. The production of natural hydraulic cement during 1901, however, decreased 2,000,000 lb. from that of 1900, and the output of slag cement also showed a large proportionate decrease.

**Slag Cement.**—The output of slag cement was 272,689 bbl., of 400 lb., valued at \$198,151, against 490,150 bbl. (\$622,490) in 1900. The average price declined strongly, in order to meet the competition of Portland cement which, in addition to its superiority for most purposes, sold at very low figures in the large manufacturing centers. There were six plants in operation, the same as in the previous year. By the decision of a board of engineers officially appointed, it has been decided that "Steel Portland Cement" cannot be substituted for Portland cement in government work where the specifications call for the latter, but is to be classed as puzzolana slag cement. The slag cement industry of the United States is given in detail in the special monograph by Mr. E. C. Eckel, later in this section.

CEMENT PRODUCTION, IMPORTS, EXPORTS AND CONSUMPTION IN THE UNITED STATES. (IN BARRELS OF 300 LB.)

THE CEMENT INDUSTRY IN THE UNITED STATES DURING 1901.

By FREDERICK H. LEWIS.

**PORTLAND CEMENT.**—The production of Portland cement during 1901 presented the same extraordinary conditions as those which prevailed during the previous year,—an enormous output, extremely low prices, and a number of new plants projected or under construction in various parts of the country. The output was considerably larger than that of the previous year, and the stock of cement on hand at the end of 1901 was undoubtedly smaller than at the end of

1900. With the enormous amount of construction work in view in all parts of the country, it seems probable that the output for 1902 will be wholly absorbed and better prices will be realized than for two years past, a result much to be desired, as profits of manufacture have been unsatisfactory; indeed the smaller and less favorably located plants have had no profits for several years.

While nothing new or novel has developed in the process of manufacturing cement in the United States, the general tendency has been to bring greater mechanical skill to bear on the development of the industry. In recent years the expert mechanical engineer has found an extremely interesting field of work in the improvement of facilities and details for the manufacture of Portland cement, and the economies realized have been due almost entirely to the skill which has been applied along this line.

The rotary kiln process has become permanently established as the distinctive American method of making cement, although it has also been used to a considerable extent abroad. The reports of the operation of rotary kilns at the Hemora plant in Germany indicate that it is quite successful in working wet materials and that the product is decidedly superior to that produced by the continuous shaft kilns previously in use.

The report on cement of Messrs. Stanger & Blount, which was read before the Institution of Civil Engineers, and the discussion thereon form a very interesting and valuable contribution to the industry. Messrs. Stanger & Blount were employed as experts by an English syndicate to examine into the American rotary process of making cement, particularly with reference to the work of the Atlas Cement Co., which uses certain devices patented by Messrs. Hurry & Seaman, in this country and in England. The English syndicate was organized to purchase the English patents of the devices and to use them in a very large plant or a series of plants promoted chiefly by the old English cement firm of J. B. White & Co. Whether the rotary process will be successful under the English conditions of materials, labor, and fuel remains to be seen, but it seems quite evident that it will be tried on a large scale in the near future. The success of the rotary kiln process for wet materials in America is not yet firmly established or clearly demonstrated. In England and the Continent the cost of fuel at the present time is undoubtedly higher than it is in America, and the success or failure of applying this process abroad, on wet materials, will be watched with much interest.

The quality of the domestic Portland cement marketed in the United States during 1901 was superior to that produced in previous years, as well as being of better quality than the foreign brands of this commodity; a fact which has been fully confirmed by tests and analyses. This has resulted from the increased application of the rotary kiln on raw materials, equally as good as those used abroad.

The methods of testing Portland cement and the proper requirements of specifications for this product, still remain a vexed question. The committee on the methods of testing appointed by the American Society of Civil Engineers, under the chairmanship of Prof. George F. Swain, has done very conscientious work during 1901 in the endeavor to develop acceptable rules. The subjects under discussion have been divided among the members of the committee, and numerous

special reports have been presented and discussed. At the close of the year the matter was in sufficient shape to make a preliminary draft of the method of tests, which will be further developed and improved during the year 1902, and will probably be reported to the Society at the close of that year. Undoubtedly the methods proposed, if adopted by the Society, will be very generally adopted by the engineering profession and will result in a much greater uniformity of tests and a much more general consensus of opinion in regard to the proper criteria to be used in judging the quality of Portland cement.

The New York section of the Society of Chemical Industry appointed a committee in April, 1901, to report on "Uniformity in Technical Analysis." This committee appointed a sub-committee to deal with the methods of analysis of materials pertaining to Portland industry, with Mr. Clifford Richardson as chairman, and the co-operation of 17 representative chemists was secured, all of whom analyzed the same samples of materials and reported to the chairman. The results obtained were subsequently reviewed by Mr. W. F. Hillebrand, of the United States Geological Survey, and together with the methods of analysis suggested by Mr. Hillebrand, were reported to the Society on December 20, 1901. The value of this report can hardly be overestimated, and its advantages to chemists engaged in this industry as a basis of standardizing their work will be very generally recognized. On account of the length of the report, it is not practicable to include even an abstract of it in these pages, and reference should be made direct to the original publication.

*New Plants in Operation.*—In Alabama, the Alabama Portland Cement Co., at Demopolis, placed three rotary kilns in operation, using argillaceous limestone.

In Michigan, the Newago Portland Cement Co. operated a 3-kiln plant at Newago, on the Muskegon river, using marl and clay in the manufacture of cement, and utilizing the water power of the Muskegon river for power purposes. The Alpena Co., at Alpena, has a plant of rotary kilns.

In New Jersey the new 10-kiln plant of the Alpha Cement Co. went into operation.

In New York, the Helderberg Cement Co., at Howes Cave, Schoharie County, placed a new plant in operation during 1901, of a nominal capacity of 1,500 bbl. per day. The raw materials are hard limestone of the Water Lime Group in New York State, and clay. The Glens Falls plant, which was destroyed by fire a year or two ago, was rebuilt and placed in operation.

In Pennsylvania, the Northampton plant, in Northampton County, operated with six standard rotary kilns, and the American Cement Co., at Egypt, placed several new rotary kilns in operation during the year.

*Plants Projected or Under Construction.*—In California, the Pacific Portland Cement Co. has under construction a modern rotary-kiln plant at Suisun, where there is a large deposit of pure limestone which will be utilized in connection with a blue-clay deposit in the marshes of that vicinity. The Pacific Co. will place three kilns at once, so arranged that seven additional kilns can be installed. Electric power developed from water power will be used throughout, and the fuel will be petroleum oils from southern California. The plant will be equipped with modern machinery and, as it will be operated under

the most advantageous conditions for power and kiln-fuel for this locality, it is expected to make cement at a moderate cost, and to be able to reduce its price on the Pacific coast to a more reasonable figure than that now maintained. The Eureka Portland Cement Co. is reported to be building, or about to build, a plant in the same locality. The California Cement & Lime Co. has been incorporated with the idea of building a cement plant in San Joaquin County, not far from Stockton. The only plant in operation at present in California is that of the California Portland Cement Co., at Colton. This plant operates two rotary kilns on hard limestone and soft clay.

In Colorado, the Colorado Portland Cement Co. and one other propose to erect plants near Florence.

In Indiana, the Lehigh Portland Cement Co. has under construction an 8-kiln plant at Mitchell. The materials to be used are hard limestone and clay.

In Michigan, the Great Northern Portland Cement Co. has under construction a large plant at South Baldwin, and the Bellaire Portland Cement Co. has been organized at Bellaire.

In Missouri, at Hanover, the Atlas Portland Cement Co. has purchased a tract of land and placed under construction a large plant to handle its Western trade. The material is hard limestone, which will be used with a suitable mixture of clay to produce a Portland cement. The St. Louis Portland Cement Co. is building a plant at Prospect Hill, near Baden.

In New Jersey the Edison Co. has a large plant projected at Stewartsville, which is expected to place cement on the market during 1902. The Capital Portland Cement Co. has been incorporated, and is reported to have purchased land near the Edison plant, at Stewartsville, for the erection of a large plant. The Marksboro Portland Cement Co. has projected a plant at Marksboro, Warren County, to use marl from White Lake.

In New York, the plant of the Alsen American Co., on the west bank of the Hudson river, near Catskill, has been under construction during the year and will probably go into operation in the spring of 1902. It is stated to be a well-equipped American plant with the improved features of an European plant.

In Pennsylvania, the Lehigh Co. has started the erection of a third plant of eight kilns near Ormrod.

In Texas, at Dallas, a plant has been projected to manufacture cement for the Southern trade.

In Virginia, the Virginia Portland Cement Co., at Craigsville, has placed contracts for doubling its original plant, and the enlarged plant is expected to be in operation during the summer of 1902.

In West Virginia, the Buckhorn Portland Cement Co., at Rollsburg, has still been unable to complete its plant, owing to financial difficulties which required the plant to be sold by a receiver. In all probability this plant will ultimately be completed and will become a feature in the market.

In addition to the above projects, several others in various parts of the country have been reported, particularly in the South, but the information is not sufficiently definite to warrant notice.

In Canada, the National Portland Cement Co. is reported to be building a large plant at Durham, Ont., with offices in Toronto.

NATURAL HYDRAULIC CEMENT.—There has been a very large sale of natural cement during 1901 and an increase in production. The Pennsylvania plants, having a natural raw material which can be utilized for this purpose, are increasing to some extent their facilities for making natural cement, and plants which have not produced it heretofore are now taking up its manufacture. The Vulcanite Co., at Vulcanite, N. J., is reported to be building, or about to build, natural cement kilns. A very excellent grade of American cement is made from a mixture of Portland and natural cement, which can be sold at a considerably lower price than for Portland cement alone. In the Ulster County, N. Y., district some consolidations of interests are reported. In Alabama, the Chickamauga Cement Co. is reported to be building a large plant at Rossville, Ga.

## THE SLAG CEMENT INDUSTRY IN THE UNITED STATES DURING 1901.

BY EDWIN C. ECKEL.

At the present time blast-furnace slag is used in three very different ways in cement manufacture and the methods should be sharply distinguished, as the resulting products are widely different in their properties. The uses of slag referred to are the following:—

(1) Granulated basic blast-furnace slag is intimately mixed with slaked lime, and the mixture is pulverized, giving a slag cement. This product, though usually called a Portland cement by its manufacturers, is unlike a true Portland in both its ultimate and rational compositions and in the processes through which it has passed. Further than this, and more important from the engineer's standpoint, a cement of this class has certain qualities which prevent its being used as an exact substitute for a Portland cement. About half a dozen plants are engaged in the manufacture of this material in the United States, while a large number of works make it in England and in continental Europe.

(2) Slag is mixed with limestone; and the mixture pulverized, calcined and reground, giving a true Portland cement. The "Universal" Portland brand of the Illinois Steel Co. is made in this manner, and the process is becoming somewhat largely employed in continental Europe, though it does not seem to have taken root in England. Absolutely no objections can be urged against cements produced in this fashion, for in composition, methods of manufacture and qualities of the product they agree entirely with Portland cements made from limestone or marl and clay.

(3) Powdered slag is added to Portland cement, either after the clinker has been ground, or during the final stages of the grinding. In this case the slag is used merely as an adulterant. While it seems certain that it can be of no benefit to the cement, it is almost equally certain that it is not actively detrimental. In fact, were the mixing and the grinding managed carefully enough, the resulting product might be regarded as falling approximately in the class of sand-cements. As it is, however, the case is simply one of adulteration carried on in order to decrease the cost of the product.

In this connection another use of slag should be referred to, though in this case the slag is added by the engineer, not by the manufacturer, and serves a distinctly useful purpose. The use alluded to is:—

(4) The addition of slag to Portland cement intended for use in sea water.

The following paper is confined strictly to a discussion of the material produced by the first mentioned use of slag resulting in a slag cement, of the class of pozzuolanic cements.

Slag cement is composed of an intimate mechanical mixture of slaked lime and granulated blast-furnace slag of suitable chemical composition; both materials being finely pulverized before, during or after mixing. The process of manufacture includes the granulating and drying of the slag, the slaking of the lime, the mixing of these materials and the grinding of the resulting cement, together with any means which may be employed for the regulation of the setting time of the cement.

The seven (or eight) slag cement mills operating in the United States advertise their product as Portland cement, a position which seems to be indefensible, even from the point of view of sound business policy. Slag cements possess some qualities which Portlands lack; and could, it would seem, be sold on their merits. So far as cost of manufacture is concerned, slag cements can be sold at lower prices than "natural" cements, though they are generally quoted at much higher rates.

The slag cements manufactured in this country are far superior to those of Europe in tensile strength, soundness, etc. Regulation of set is invariably practiced, the result being that American slag cements set as rapidly as Portlands. Most of the American plants are directly connected in ownership, with iron companies. This is necessary if a supply of proper slags is to be obtained.

*Composition of the Slag.*—The slag used in cement manufacture must be basic blast-furnace slag. Tetmajer, the first investigator of slag cements, announced as the results of his experiments (a) that the hydraulic properties of the slag increased with the proportion of lime contained in it, and that slags in which the ratio  $\frac{\text{CaO}}{\text{SiO}_2}$  was so low as to approach unity were valueless for cement manufacture; (b) that, so far as the alumina content of the slag was concerned, the best results were obtained when the ratio  $\frac{\text{Al}_2\text{O}_3}{\text{SiO}_2}$  gave a value of 0.45 to 0.50; and (c) that with any large increase of alumina above the amount indicated by this value of the alumina-silica ratio, the tendency of the cement to crack (when used in air) was increased.

Prost, at a later date, investigated the subject, using for experiment several commercial slags and also a series prepared from pure  $\text{CaO}$ ,  $\text{SiO}_2$ , and  $\text{Al}_2\text{O}_3$ . He decided that the hydraulic properties (both as regards rapidity of set and ultimate strength) of the slag increased as the proportions of lime and alumina increased; and failed to find any indication that a high alumina content causes disintegration. His best results were obtained from slags having the compositions respectively of  $2\text{SiO}_2$ ,  $\text{Al}_2\text{O}_3$ ,  $3\text{CaO}$  and  $2\text{SiO}_2$ ,  $\text{Al}_2\text{O}_3$ ,  $4\text{CaO}$ .

Mahon, in 1893, made a series of experiments to determine the value (for cement manufacture) of a large series of the slags produced by the furnaces of the Maryland Steel Co.; and found that the slags giving the best results were two having respectively the following compositions:—

(1)  $\text{SiO}_2$ , 30%;  $\text{Al}_2\text{O}_3$ , 17%;  $\text{CaO}$ , 47.5%; S, 2.38%; and (2)  $\text{SiO}_2$ , 25.3%;  $\text{Al}_2\text{O}_3$ , 20.1%;  $\text{CaO}$ , 48%;  $\text{MgO}$ , 3.28%; S, 2.63%.

The ratios of  $\frac{\text{CaO}}{\text{SiO}_2}$  and  $\frac{\text{Al}_2\text{O}_3}{\text{SiO}_2}$ , calculated for these slags are:—

$$(1) \frac{\text{CaO}}{\text{SiO}_2} = 1.58; \frac{\text{Al}_2\text{O}_3}{\text{SiO}_2} = 0.57; \text{ and } (2) \frac{\text{CaO}}{\text{SiO}_2} = 1.9; \frac{\text{Al}_2\text{O}_3}{\text{SiO}_2} = 0.79.$$

At the close of the experiments Mahon recommended that slags be used even slightly higher in alumina than those above quoted.

The specifications under which slag from the furnaces is accepted by the cement department of the Illinois Steel Co., are:—

*Physical Condition of the Slag.*—Slags allowed to cool slowly are only feebly hydraulic, whatever be their chemical composition, hence for use in the manufacture of slag cement, they must be cooled very rapidly. In practice this is effected by bringing the slag, immediately upon issuing from the furnace, in contact with a stream of cold water. The physical effect of this sudden cooling is to granulate the slag into porous particles. The chemical effects are two in number: One, the reason for which is not yet well understood, is to make the slag (if it be of suitable chemical composition) energetically hydraulic; the other, is to remove a portion of the sulphides in the form of hydrogen disulphide. Both of these effects are beneficial, from the point of view of the slag-cement manufacturer, and the first is absolutely necessary. As the sulphides are probably the cause of the disintegration of slag cement when exposed to dry air, the removal of even a part of the sulphur is a decided benefit.

In regard to the physical condition of the slag, Candlot further states that "the slag issuing from the furnaces at the beginning and end of a discharge is usually rejected, because of the bad effect of the chilling which attends its slow movement. For the same furnace, the spongier and bluer the slag, the more basic it is; the blacker and more vitrified, the less fit for cement."

*Proportions of Lime and Slag.*—Prost, in consequence of his experiments with various proportions of lime, advocated the proportion, to secure the best results, of from 35 to 40 parts of lime to 100 parts of slag. He also stated that the amounts of lime used in actual practice, for each 100 lb. of slag were: at Choindez, 40 to 45 lb.; at Donjeux, 40 lb.; at Brunswick, 33 lb.; and at Cleveland, 33 lb. Mahon, in reporting his experiments for the Maryland Steel Co., states that the best results were secured by the use of 25 parts of lime to 100 parts of slag, by weight. In the manufacture of slag brick, which is in reality merely a branch of the slag-cement industry, the amount of lime added may fall as low as 10 lb. to 100 lb. of slag.

*Composition of the Lime.*—According to Prost, there is no gain in tensile strength if hydraulic lime be used in place of common lime. There is, however, another benefit to be derived from this practice; for the cements made with hydraulic lime are less liable to fissure and disintegrate when used in air than are those in which a fat lime has been used. The lime used should not carry much magnesia, for this latter constituent, even though it may not be actively detrimental, is an inert material, and it should be thoroughly and evenly burned, as unburned lumps are of no service to the cement. It must then be slaked with care, as unhydrated portions would be actively detrimental. If possible, the slaked lime should not be used immediately, time being given for the air-slaking of any lumps which may have escaped hydration. The resulting material can best be mixed with the slag if given a preliminary bolting which process will remove both unburned cores and unslaked lumps. Frequently this sieving is followed or preceded by light grinding.

*Chemical Composition of Slag Cements.*—The ultimate composition of the material will, of course, be brought out by chemical analysis, but the fact that it is merely a mechanical mixture will not be shown in the ordinary report of such an analysis. Slag cement, when ready for sale, is a mechanical mixture of lime

hydrate ( $\text{Ca}_2(\text{OH})_2$ ) and a calcium aluminum silicate ( $x\text{SiO}_2, \text{Al}_2\text{O}_3, y\text{CaO}$ ). In addition to the essential ingredients noted above, certain others of less amount usually occur. The most important of these in the effect it produces on the quality of the product, is sulphur, which is obtained from the slag in the form of sulphides of lime or iron. To the presence of these sulphides is due, in large part at least, the disintegration of slag cements when used in dry air. If the cement be used for construction in water, their presence is of much less importance, and the total sulphides may run as high as 5% without seriously impairing the quality. Several per cent. of iron oxide obtained from the slag are commonly present. Magnesia also occurs, derived from the slag or the lime. It is inert, if not positively detrimental, and the amount should therefore be kept as low as possible.

In addition to the ingredients mentioned above, a percentage, usually small, of other compounds may be found, which have been added by the manufacturer during some stage of the process for the purpose of increasing the rapidity of set of the cement. These substances will be later discussed in the section relating to the means of hastening set.

Table II. contains the analysis of a number of American and European slag cements, as given by various authorities. It will be seen that, despite the apparently great variations in practice, the ultimate composition of the finished cement falls within quite narrow limits. The range in composition of a good slag cement may be considered to be about:  $\text{SiO}_2$ , 22 to 30%;  $\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$ , 11 to 16%;  $\text{CaO}$ , 49 to 52%;  $\text{MgO}$ , less than 4%; S, less than 1.5%; ignition loss, 2.5 to 7.5%.

TABLE II.—ANALYSES OF SLAG CEMENTS.

**MANUFACTURING METHODS.**—The preliminary preparation of the materials includes the burning and slaking of the lime, and the granulating and drying of the slag. After these operations have been carried out, the materials may either be mixed immediately and the mixture ground to proper fineness in a series of mills; or the slag and lime may be ground separately, mixing being deferred until the grinding is completed. Regulation of set is almost invariably practiced at American plants, and the materials necessary to accomplish this may be added at various points in the process. Though slag-cement manufacture is simple, it will be seen that there is considerable latitude for variations in practice at different

plants. Brief sketches of the general methods in use at various plants will therefore be given; followed by a more detailed discussion of certain points of particular interest. In the granulation of the slag and the slaking of the lime little variation in practice is possible. The drying of the slag, however, is carried on in very different ways at different plants. It is an important element in the cost of the finished product, and will therefore be discussed in considerable detail. Methods of grinding, and of regulation of set, are also of both theoretical and practical importance, and are discussed at some length in the following pages.

*General Practice.*—The Maryland Cement Co.,<sup>1</sup> at Sparrows Point, Md., obtains the slag from the furnaces of the Maryland Steel Co. The slag is dried in Ruggles-Coles dryers; and, after mixing with the slaked lime, is ground in discontinuous pebble-mills. Mahon's experiments, preliminary to the establishment of this plant, are discussed on an earlier page.

The slag-cement plant of the Illinois Steel Co., Chicago, Ill., obtains its slag from the blast-furnaces of that company. The specifications under which this slag is received, with analyses showing its actual range in composition, will be found on a preceding page. After granulation and drying in a specially designed dryer the slag receives its preliminary reduction in Griffin mills. Meanwhile the lime has been slaked as described in detail on a later page of this paper, caustic soda being added to regulate the set of the product. The ground slag and this prepared lime are then mixed, and the mixture receives its final reduction in Davidsen tube-mills.

At the plant of the Birmingham Cement Co.,<sup>2</sup> at Ensley, Ala., slag is obtained from the furnaces of the Tennessee Coal & Iron Co., located in nearby towns. The slag is granulated at the furnaces. On arrival at the mills, carrying about 40% of water, it is dried in Ruggles-Coles dryers. Two of these, of the A2 style are in operation. After drying, the slag and slaked lime are fed together to West ball mills, four of which are in use, and the mixture is finally reduced in West tube mills.

The Southern Cement Co., at North Birmingham, Ala., dries its slag in a style A2 Ruggles-Coles dryer. The dried slag is crushed in a Kent mill. After mixing with the slaked lime, the final reduction takes place in West tube mills. Two brands of slag cement are marketed. One, a normal slag cement, is said to average about CaO 55%, Fe<sub>2</sub>O<sub>3</sub>, Al<sub>2</sub>O<sub>3</sub> 12%, SiO<sub>2</sub> 27%. The other brand is quicker setting and carries about 10% less CaO and about 10% more SiO<sub>2</sub>. This high silica content is due to the addition of a very highly siliceous rock, probably a pure crushed quartz.

At Skinningrove, England, slags were used of a composition varying between the following limits: SiO<sub>2</sub>, 30 to 32%; CaO, 30 to 33%; Al<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>, 25 to 28%. The slag on issuing from the furnace, was run into water; ground, before drying, under edge runners; and dried on iron plates in a drying chamber. The dried material was ground under millstones; sieved; and mixed with lime (which had been slaked and screened) in the proportions usually of lime 33 lb.

<sup>1</sup> Lewis, F. H., *Cement Industry*, p. 184.

<sup>2</sup> Eckel, E. C., *Engineering News*, Jan. 23, 1902.

slag 100 lb. The resulting cement varied in composition between the following limits:  $\text{SiO}_2$ , 24 to 26% ;  $\text{CaO}$ , 45 to 47% ;  $\text{Al}_2\text{O}_3$ ,  $\text{Fe}_2\text{O}_3$  20 to 22%.

At Vitry, France, the slag is struck by a jet of water immediately upon issuing from the furnace and carried by it into a masonry storage tank. From this tank the granulated slag is elevated and carried to the mill. Five dryers of the style shown in Fig. 1 are employed, the dimensions being slightly different from those used at Choindez. After drying the slag is sieved, to remove the coarser particles, passed through six mills of different types, and again sieved. After having been thus reduced to the proper fineness, it is mixed with the slaked lime in ball mills operated discontinuously; the proportions being about 40 lb. lime to 100 lb. of slag.

*Regulation of Set.*—Slag cements set very slowly, relative to Portlands. As

FIG. 1.—STATIONARY SLAG DRYER AT VITRY, FRANCE.

this interferes with their use for certain purposes, many attempts have been made, by various treatments, to reduce their setting time. There is, unfortunately, another reason why the manufacturer should desire to hasten the set of his product. Most of the slag cements sold in this country masquerade as Portland and it is desirable to the manufacturer therefore to make such of their properties as are brought out in ordinary tests or analyses approximate to those of true Portland cement. The set of slag cements can be hastened by the addition of pozzuolanic materials. Of these, burned clay, certain active forms of silica and slags high in alumina are the cheapest and most generally obtainable. The most important method of regulation is, in this country at least, the Whiting process, which is followed at two large American plants.

United States Patent No. 544,706, issued in 1895 to Jasper Whiting, covers

the use of "caustic soda, potash, sodium chloride, or equivalents or any substance of which the latter are ingredients," added either as aqueous solutions or in a dry state at any stage of the process of slag-cement manufacture. In the specifications accompanying the application for this patent, the patentee states that, in the case of dry caustic soda, the amount added will vary from 0.125 to 3%, "depending chiefly upon the use for which the cement is intended." The patent was subsequently conveyed to the Illinois Steel Co., and the process covered by it is used by that company in the manufacture of its "Steel Portland" cement. A license has been issued to the Brier Hill Iron and Coal Co., of Youngstown, Ohio, under which license this company manufactures its "Brier Hill Portland" cement.

The process, as practiced in the slag-cement plant of the Illinois Steel Co., Chicago, Ill., is as follows: The quicklime used is obtained from the calcination of Marblehead or Bedford limestone and carries less than 1% MgO. On its arrival at the mill it is unloaded into bins, beneath which are placed two screens of different mesh, the coarser at the top. A quantity of lime is drawn upon the upper screen, where it is slaked by means of the addition of water containing a small percentage of caustic soda. As the lime is slaked it falls through

FIG. 2.—RUGGLES-COLES DRYER.

the coarse screen onto the finer screen, through which it falls into a conveyor which carries it to a rotary dryer. After heating, the resulting slaked and dried lime is carried by elevators to hoppers above the tube mills, where it is mixed in proper proportions with the granulated slag, which has been dried and powdered.

*Drying.*—The drying of the slag is one of the most important steps, economically, in slag-cement manufacture. The large percentage of water carried by granulated slag must be evaporated almost entirely, if good results are to be expected from the grinding machinery. Three types of dryers are used in common practice.

The Ruggles-Coles dryer (see Fig. 2) consists of two concentric hollow cylinders bolted together and revolving on an axis slightly inclined from the horizontal. The outer cylinder is made of steel plates, the longitudinal seams having butt joints with inside lapping straps. The inner cylinder, which is also made of steel, is connected with the outer cylinder at the center by heavy cast-iron arms, *A*, solidly riveted to both cylinders; and at each end, by two sets of adjustable or swinging arms, *B*, which prevent expansion and contraction from affecting the rivets or joints. At the head or upper end the inner cylinder

projects beyond the outer cylinder, passing into a stationary head or air chamber, *E*, to the hot air flue, *D*, of the furnace, *G*, with which it is connected. At the lower or discharge end is another stationary head, *E*, forming an air chamber, through an opening in the bottom of which the dried material is discharged. This head is provided with a damper to regulate the temperature which gives perfect control.

The outer cylinder is set at an inclination of about 0.375 in. to the foot. It is secured to two heavy rolled steel bearing rings, *F*, which rest and revolve upon eight bearing wheels supported by oscillating arms or rockers. The lateral motion of the cylinder is taken up by four thrust wheels. The dryer is revolved by a cast gear, *H*, secured to the outer cylinder, and this is driven by a shaft and pinion, *K*, extended beyond the end of the machine and supported in two babbitted journal boxes fitted to the frame. The entire machine is fitted and secured to a heavy frame of 8-in. "I" beams braced and framed together and usually set on a concrete foundation. The exhaust fan is placed where most convenient to drive and is connected with the outer cylinder by suitable flue, *L*. The furnace, *G*, is built independent of the machine and connected with the head end of the inner cylinder by an iron flue, *D*, built with fire brick. A specially designed burner is substituted for the furnace for the use of oil, gas, or powdered coal.

The heated air passes through the inner cylinder (shown by dotted lines in the illustration) and returns between the inner and outer cylinders to the fan. The direction of the hot air current also is shown by arrows. The slag is fed into the space between the inner and outer cylinders, through a spout *C*, in the stationary head at the upper end of the machine. It is picked up by buckets or carriers fastened to the inner surface of the outer cylinder and carried partly around during the rotation of the dryer. On dropping from these buckets it falls and is caught on the flights fastened to the outer surface of the inner cylinder, which carry it partly around and then drop it to the bottom of the outer cylinder, when the cycle commences again. While these movements of the slag are occurring, it is being dried both by the heated air in the space between the two cylinders and by contact with the warm outer surface of the inner cylinder; and it is also being carried slowly toward the lower (discharge) end of the machine.

The following table shows working results in the use of the Ruggles-Coles dryer on granulated slag:—

| User.                        | Original<br>Percentage<br>Moisture. | Final<br>Percentage<br>Moisture. | Water<br>Evaporated<br>per Hour. | Dry Material<br>Delivered<br>per Hour. | Coal Used<br>per Hour. | Water Evap-<br>orated per<br>Lb. of Coal. |

The Holst dryer is used at Donjeux and Mallstadt, and consists essentially of a sheet-iron cylinder 9 m. long and 0.8 m. in diameter, into which the slag is fed automatically by a screw feed. In the cylinder a helical screw revolves on a hollow central shaft, causing the slag to advance slowly through the cylinder. The fireplace is below and near one end of the cylinder and the heat is caused

pass under the cylinder to the other end; thence through the hollow shaft to the stack in a direction contrary to that in which the slag is moving. The cylinder is protected from the direct flame by brickwork. This apparatus dries from 7 to 8 metric tons of slag per day with a coal consumption of about 5% of the weight of slag dried.

At Vitry, France, a simple and effective non-rotary dryer, operated by gravity, is employed, plan and section of which is given in Fig. 1. It consists of drying compartments (each of which is lettered, *A, B, C, D*, in the plan) arranged about a central flue (*C, D, C, D*, in plan), through which passes the heated gases from a furnace. The central flue is 1 m. square; the drying compartments 0.5×1 m. in area; and both are 7 m. in height. Each of the drying compartments contains 10 sheet-iron plates (of which only six, *E*, are shown in each compartment of the section). These plates are inclined and so arranged that the wet slag, shoveled in at the top of each compartment, descends by gravity and finally issues from the lowest plate in the heaps, *F*, from which it is shoveled and sent to the grinding mills. According to Prost, a dryer of this type and size will dry from 12 to 15 metric tons of slag per working day. From 6 to 6.5 lb. of coke are necessary to dry each 100 lb. of slag.

*Pulverizing and Mixing.*—The greatest differences in practice exist in the processes for grinding and mixing the slag and lime. The statement has been made, in several publications, that the differences in hardness between dry granulated slag and slaked lime is so great that it is impracticable to pulverize them together in a continuously operated mill. A number of plants, therefore, have installed small discontinuous mills, each of which is charged, locked, operated for a sufficient time to pulverize both constituents of the mixture, and discharged. The disadvantage of this intermittent system are obvious and it seems especially unfitted for American conditions. The statement that no continuously operated mill was able to handle the mixture seemed inherently improbable, in view of the great variety of material successfully handled by the modern ball and tube mills when operated continuously in Portland cement practice. I referred the question to a leading firm of manufacturers and was informed that nothing in their experience justified the unfavorable conclusion; and that their continuously operated tube mills had successfully pulverized mixtures of slag and lime. It seems probable that the most economical practice would be to send the dried slag through a small crusher, Griffin mill or ball mill; mixing the crushed slag with lime, and completing the mixture and reduction in continuously operated tube mills. Whatever system of reduction is employed, it is necessary that the slag be dried as completely as possible and, with modern dryers, the amount of moisture in the dried slag can be economically kept well below 1%.

*Identification of Slag Cement.*—Slag cements may usually be distinguished from Portland cements by their lighter color, inferior specific gravity, and slower set. They show on analysis lower lime and higher alumina percentages than Portlands, and usually contain an appreciable amount of calcium sulphide. Owing to the presence of this last named constituent, a briquette of slag cement left for some days in water will show upon fracture a decided greenish tint; if

it has been exposed to salt water, this tint will be much more marked, and the odor of hydrogen sulphide will be observed. Two things should be noted, however, in this connection. The presence of sulphides though usual is not a necessary occurrence in slag cements; and, on the other hand, sulphides are occasionally present in Portland cements, being formed from the sulphates in case the flame of the kiln is not sufficiently oxidizing.

**Color.**—Slag cements are usually much lighter in color than the Portlands, varying from a bluish white to lilac. The color of the cement depends partly upon the color of the slag and the lime, but more largely upon the relative proportions of the two ingredients. Slag cements do not stain masonry, in which respect they have an advantage over Portlands for certain uses.

**Specific Gravity.**—Cements of this class are lighter than Portlands, their specific gravity usually ranging from 2.7 to 2.8. This gives a greater bulk for the weight, but on the other hand it reduces the density of the set cement, which is not desirable for some purposes.

**Rapidity of Set.**—Normally slag cements are slower setting than Portlands. Whether this property is a disadvantage or not will depend on the use to which the cement is to be applied. As before mentioned, the rapidity of set increases naturally with the amount of alumina in the slag. Set can be artificially hastened by the addition of pozzuolanic material to the cement; burned clay, certain active forms of silica, slags high in alumina, etc., are additions which are both effective and cheap. The treatment of the cement during manufacture with alkalies to accelerate the set, has already been discussed.

**Strength.**—While slag cements fall below high-grade Portlands in tensile strength, good American slag cements develop sufficient strength to pass the usual specifications for Portlands. Tested neat, they do not approximate so closely to the Portlands as they do if tested in 2:1 or 3:1 mortars. Part of this property may be due to the fact that they are, in general, ground finer than Portlands, especially than foreign Portlands. Prof. W. K. Hatt recently made a large series of tests on American slag cements, and reported that there was no noticeable deficiency in strength of briquettes kept in air as compared with those kept in water. Other investigators have arrived at opposite conclusions; and it is probable that these conflicting results arise from differences in the chemical composition of the various brands tested.

**Resistance to Mechanical Wear.**—Slag cements are notably deficient in this property, and are therefore not available for use for the surfaces of pavement, floors, etc., where this quality must be highly developed; they seem to be well fitted, however, for pavement foundations, or indeed for any work which will not be exposed to dry air, and in which a high strength is not necessary.

**Plants.**—Of the seven slag-cement factories now in operation in the United States, two each are located in Alabama and New Jersey, and one each in Illinois, Ohio and Pennsylvania. Two new plants are projected, and may be erected and in operation before 1903; these are to be located respectively in Alabama and Pennsylvania. Most of the plants now in operation are connected closely in ownership with the furnaces from which their slag is obtained. This condition is almost a necessity, since common ownership or control furnishes the only

possible guarantee that a sufficient supply of slag, of proper quality, will be always available.

*Price.*—The selling price of slag cements is highly variable, as can be understood from statements made on previous pages. Whenever possible, they are sold as Portlands; and in that case approximate in price to cements of that class. When necessary, however, they are marketed at prices below those of natural cement plants. Taking the entire annual product into consideration, its price per barrel will probably average about 20 to 25% higher than the best brands of natural cements (New York Rosendale). The industry affords very fair profits and the output in the United States is increasing steadily.

American slag cements are certainly superior in strength, uniformity and rapidity of set to European slag cements. Slag cements are not, however, Portland cements; and the sooner this fact is recognized and publicly admitted by their manufacturers, the better will be the prospects of the industry. For, though slag cements are entirely unfitted for many uses to which Portland cements may be applied, there are certain uses for which they are peculiarly well adapted, and if, for any particular use, a slag cement is as good as a Portland, its lower price will of necessity remove any danger of Portland competition.

## CHROMIUM AND CHROME ORE.

THE production of chrome ore in the United States during 1901 was very small, although an advance on 1900, as that year produced none. The only mines in the country which were worked during the year being the California mines, which produced a total of 498 long tons, valued at \$7,740. The imports of chrome ore during 1901 were 30,112 long tons, against 17,542 long tons during 1900, an increase of 2,570 tons during the year, the average value per ton being slightly higher in 1901 than in 1900—\$18.05 and \$17.39, respectively. The larger part of the chrome ore used in the United States is consumed in the manufacture of iron and steel products, for details of which reference may be had to the section devoted to "Iron and Steel" later in this volume. The consumption and demand for ferrochromium products were so disappointing during 1901 that several works formerly producing chrome steel and the alloys have altered their machinery for the manufacture of ferrotungsten and ferrotitanium as a substitute, because tungsten and titanium ores are more easily obtainable, both as to quantity and quality. The chrome ores for use in steel making are generally imported from Turkey. The total production of ferrochromium during 1901 was about 1,200 long tons, which commanded a smaller price than in 1900. Ferrochromium continues to be used chiefly in the manufacture of steel stamps, and while titanium steel has been substituted to some extent, it has not been very successful, owing to the difficulty of fusing titanium at the melting point of steel. The Willson Aluminum Co., of Kanawha Falls, W. Va., and Holcomb Rock, Va., makes an alloy of 50% Cr and 15% Ti, which has very great tensile strength as well as resistance to abrasion and shock. The use of chrome ore as a lining for furnaces has increased slightly during the year, and it is likely will continue to increase, for the life of such linings and bottoms is several times greater than any other known refractory material and its insertion is not difficult. In some instances the ore is made into bricks, but a very effective lining is produced by filling the spaces between the larger lumps of ore with the fines, tamping the whole to a fairly even surface.

The Chrome Steel Co., of Brooklyn, N. Y., early in 1902 determined to re-

move its plant to Cartaret, N. J., where a large universal forging machine of German design and manufacture will be installed.

PRODUCTION, IMPORTS AND CONSUMPTION OF CHROME ORE IN THE UNITED STATES.

(a) From the official statistics of the respective countries, except for the United States, which are our own. (b) Exports. (c) Statistics not yet published. (d) Exports from Salonica and Smyrna. (e) Exports from Salonica and Kosovo.

*Canada.*—The production of chrome ore during 1901—reported as exports during that year—amounted to 1,595 metric tons, valued at \$25,414, against 2,120 metric tons, valued at \$27,000 during 1900. The deposits of chrome ore in Coleraine, Province of Quebec, continue to furnish most of the product. The ore, consisting of chromic iron ore, is very easily mined, and is said to average 50% Cr<sub>2</sub>O<sub>3</sub>. No shipments have been made from the chrome deposits on Port au Port Bay, Newfoundland, for some time.

*Greece.*—The Bourdaly mines, at Thasala, 20 miles from the battlefield of Velstino in the Kassidiari ranges, produce annually about 3,000 tons of chrome iron ore, valued at 70 fr. per ton. The product is shipped mostly to Austria and utilized in the manufacture of ferrochromium. The mineral occurs in compact masses in a white or grayish colored earth in contact with serpentine, rarely with quartz or schist, and the ore analyzes Cr<sub>2</sub>O<sub>3</sub> 32.3%, FeO 41%, Al<sub>2</sub>O<sub>3</sub> 16%, ranges near the famous silver mines of Kissos, and deposits on Tinos Island SiO 8%. Chrome iron ore has also been discovered in Eubœa in the Pelion have been reported.

*New Caledonia.*—(By F. Danvers Power.)—Chromite when naturally broken up *in situ* is known in the trade as "alluvial chrome," and when massive it is termed "rock chrome." The alluvial variety is mostly sought, as being in separate grains it is not only easier to mine than the rock chrome, but requires no crush-

ing prior to washing. Furthermore the impurities that get in the joints and cleavage planes of the mineral are more easily decomposed and removed when washed. By far the greater part of the rock chrome mined can be beneficiated by hand dressing for the market, there being no adequate plant in the colony to deal with the impure rock chrome.

The output of chrome ore from New Caledonia in 1901 was 17,451 metric tons, as compared with 10,474 metric tons in 1900. The exports of chrome ore during 1901 were 16,586 metric tons, against 10,474 metric tons in 1900.

The principal deposits of chromite worked in New Caledonia are found in the serpentine of the south end of the island. The longer axis of the large lenticular open cuts from which the ore has been extracted run in the same direction, and many of them appear to be in the same line, or on parallel lines. In these deposits when prospectors seek large bodies of ore that are capable of being worked by open cuts, no trouble is taken to trace the continuity of any one body after the ore proves too poor or too small to work, consequently chromite is still found, both at the ends and bottoms of the excavations. The serpentine occurs in bands, and the chromite occurs between the bands and in the cross joints. A sharp line generally exists between the bands of the serpentine and the chromite, and, while there is no gradual shading off in the value, there is in quantity. Chromite is one of the most persistent accessory minerals to the serpentines and peridotites in New Caledonia and is found pretty thickly peppered through the rocks in the neighborhood of the deposits. An idea of the size of the deposits of chrome ore may be obtained when it is stated that over 20,000 tons have been extracted from one of these excavations. The ore is generally washed in sluice boxes by shoveling it against the stream; by this means it is brought to the desired grade of 50% or more, it is then drained, dried in the air and bagged. One operator placed a vertical box fitted with inclined shelves below his first sluice box in order to stir up the finer particles after having separated the coarse material, but this has now given place to a round buddle with a center overflow and an outside discharge made automatic by the set of the scrapers. By this means about 1,000 lb. of crude ore is washed per hour.

*New South Wales.*—The exports of chrome ore from New South Wales in 1900, amounted to 3,577 metric tons, against 5,327 metric tons in 1899. The chrome iron ore mines are all in the Gundagai district, and the exhaustion of the smaller deposits accounts very largely for the decreased production during 1901. The principal mines in operation are those of Messrs. Quilter Bros., and Mr. J. C. Morley, at Mount Lightning, which appear to persist with depth. With adequate railway facilities, other known deposits in the State could doubtless be worked profitably, but until then the output is likely to be limited.

*New Zealand.*—The exports of chrome ore produced by the mines near Croixelles Harbor, during 1900 amounted to but 28 tons, valued at \$550. These deposits occur in a belt of soft serpentine, underlying the Maitai limestone. The chief workings are about 1,200 ft. above sea level. The ore occurs in elliptical or lintel-shaped masses, with no regularity of occurrence. The deposits which have not as yet been proved beyond a limited depth, are at Onatea, Nelson, on the south side of Croixelles Harbor.

*Turkey.*—The production of chrome ore for Turkey for 1900 was 9,749 metric tons. Late in 1901 it was reported that the chrome mines of Elleshen, the first station on the Uskub Mitrovitza railway line were on the market for sale. The mine is situated in a fairly civilized part of the country and is said to be very rich, the ore existing in enormous blocks. Some years ago the very large output of the mine was cut down to a considerable extent by the inrush of a stream which, while comparatively inexpensive to divert to another channel, was too great an undertaking for the owner's limited resources. It is said that very little capital would be required to open up a valuable mine.

Details of the foreign works producing ferrochromium and other alloys in 1900-1901 are summarized in the subjoined table:—

| Name.                                        | Locality.       | Source of Power. | Available H. P. |
|----------------------------------------------|-----------------|------------------|-----------------|
| Société Electro-Metallurgique Française..... | Le Praz.....    | Water.....       | 12,500          |
| Société Electro-Chimique de la Romanche..... | Livet.....      | Water.....       | 12,000          |
| Acetylen Gas Gesellschaft Wien.....          | Merau.....      | Water.....       | 2,400           |

Ferrochromium is also made by the Vauntin-Goldschmidt process at Essen, Germany, and an Italian company is about to apply 1,500 H.P. at Darfo, in northern Italy, to the production of steel by the Stassano process.

#### TECHNOLOGY.

For notes on methods of analysis and former German practice in the manufacture of ferrochromium and chrome steel, reference should be had to Volumes VIII. and IX. of THE MINERAL INDUSTRY, and alloys of chromium with iron and steel are noted in the paper "Iron and Its Alloys," elsewhere in this volume.

*Chromite as Hearth-lining for Furnaces.*—In a paper read by William Glenn before the American Institute of Mining Engineers, February, 1901, reference is made to a bottom of a copper smelting furnace, which has been in use for nearly a year without any apparent deterioration. To contain the chromite, a cast iron basin was constructed with surrounding flange, the outer edges of which coincided with the exterior walls of the water-jacket, with ribs to reinforce the basin, which is an inverted arch of 36-in. chord, and 12-in. versed sine, and 1-in. in thickness (the flanges are 1.5 in. thick). Each of the two sections is 5 ft. 7 in. long, and each is reinforced by three 1-in. ribs, the sections being joined by bolts drawing up two of the ribs against an asbestos gasket. The two outer ends of the basin were closed by segments cast with the sections and the basin was supported by 10 jack-screws placed under its flanges. The chromite (Turkish ore containing 52%  $\text{Cr}_2\text{O}_3$ ) was of all sizes, from 10-in. cubes to dust, and was laid in lumps wedged by smaller pieces, with fines and dust scattered through the interstitial spaces, the whole then being well tamped into place. No mortar or binding material was used. Over the chrome bed was laid a layer of 8-in. fire brick on end. Apparently 44% chrome iron ore would be as serviceable as the Turkish product. As the campaign was made, using a very basic slag, the ore was tested under the most severe conditions; an ordinary fire-brick or

clay bottom under such conditions would have a life of little more than a week. A blister-copper furnace whose bridge-wall was constructed of chrome ore at about the same time as the smelting furnace, has shown no deterioration, and the author suggests the use of chrome ore as a lining for copper converters. The Selby Smelting & Lead Co., at Selby, Cal., has for years used a lining of California chrome iron ore, in crude lumps, wedged into shape with smaller particles and then cemented in weak spots with a mortar made of 10 parts of chrome iron ore to 1 part of plastic clay. This lining lasts for months while in use in copper matting and concentrating furnaces, and while weak spots develop owing to irregularities in the ore, they are patched, without much difficulty.

Geo. G. Blackwell, Sons & Co., Ltd., of Liverpool, England, claim to supply all furnaces in England and on the Continent with their special furnace lining, which is composed of chromium, magnesia, alumina and silica, and is said to be very refractory. The agent for the United States is the Harbison-Walker Co., of Pittsburg, Pa.

*Chromite Bricks.*—Chromite bricks as refractory material have found limited use only, owing to the fact that chrome iron ore shows a variable composition even when taken from a single mine, and also on account of their high cost. For the most refractory bricks no binding material is used except that which accompanies chromite in the form of impurities. In lower grade material, however, several binding mediums may be used, such as lime and clay or lime and bauxite in the proportions of 2% CaO and 25% clay or bauxite, a process covered by the United States Patent No. 578,351, 1901. A German Patent No. 71,067, 1900, has been issued for the use of gypsum and aluminum sulphate in the proportion of 2% of the former and 1% of the latter. This mixture is said to possess an advantage in that it gives plasticity to the mass, and also renders it but slightly more fusible, as when heated, the gypsum and aluminum sulphate are converted into CaO and  $Al_2O_3$  with a consequent reduction in percentages to 0.85 and 0.15, respectively.

*Electrolysis of Chrome Ores.*—Metallic chromium is now being produced commercially at Essen, Germany, by the Goldschmidt aluminum reduction process. Several hundredweight of the metal made in a large crucible, occupies about half an hour for its reduction. The special value of metallic chromium in steel making is its freedom from carbon and by its use steels high in chromium and low in carbon can be manufactured. Ferrochromium, which has heretofore been used for this purpose, contains from 40 to 65% Cr and from 4 to 8% C, which precludes the manufacture of a low carbon chrome steel. In fact for a steel containing 2.5% Cr, metallic chromium must be used if the carbon in the steel is to be below 0.2%. In the manufacture of open-hearth steels, when ferrochromium is used the loss of chromium by oxidation amounts to about 25%; with metallic chromium, however, the loss is much smaller. The metal is most valuable in the manufacture of crucible steels of from 1 to 2% Cr content and for higher chrome products up to 10% Cr. Steels of even higher chromium percentage are now under experiment for the manufacture of special tools.

Dr. Neumann obtained a good deposit of chromium on a carbon or metal

<sup>1</sup> *Zeitschrift fuer Elektrochemie*, 1901, 7 (48), 656-661.

cathode with a divided cell, containing a chromium salt at the cathode and an acid or saline solution at the anode. With chromic chloride solutions containing 10% Cr a current density of 0.9 ampere per sq. dm. gave chromic oxide only, while from 1.8 to 7.2 amperes gave a mixture of oxide and metal and from 9 to 18 amperes pure metal; under the last-named conditions current efficiency of 38% was obtained. The temperature seems to have but little effect on the current efficiency, but above 50°C. the metal is deposited as a black powder. A solution with 16% Cr yielded 57% efficiency, which was increased to 89.5% by changing the solution on the anode cell. With chromic sulphate the best conditions were from 6.7 to 8.5% Cr and a current density of from 13 to 23 amperes per sq. dm., giving an efficiency of from 84.6 to 86%. The acetate solution did not give as satisfactory results. The metallic deposits are of bright color and fairly lustrous but due to films of oxide it has a tendency to flake. The metal is hard, brittle and very pure, containing only 0.1 or 0.2% Fe. The decomposition potential of chromic sulphate of five times normal strength is 1.898 volts, while for chromic chloride of eight times normal strength it amounts to 1.685 volts. It is necessary, however, to use at least double these electromotive forces.

A number of patents have been applied for and granted during 1900 and 1901 in various countries of the world for new electrolytic and other ferrochromium processes. The Société Générale des Aciers Fins, of Paris, France, has obtained French Patent No. 6,655, of 1901, for a method of making chrome steel in the open-hearth furnace. P. Straneo<sup>2</sup> confirms by experiment the claims made in the patents of Street, that a quicksilver electrode gives better results than a platinum one, when used for the electrolytic reduction of chromium oxides and salts.

The Chemische Fabrik Griesheim Electron, of Frankfort-on-Main, Germany, obtained German Patent No. 12,250, of 1901, for the production of chromium compounds and alkali by the electrolysis of salts of alkali with ferrochrome anodes. William H. Greene and William H. Wahl, of Philadelphia, Pa., obtained United States Patent No. 688,510, of December 10, 1901, for a method of producing chromium, which consists in incorporating silicides with metallic oxides, the heat of formation of which is less than that of the oxides of either element of the silicides, and subjecting the mass to heat, and thereby effecting the primary reduction of the oxides by the chemical energy of both elements of the silicides.

A novel form of electric furnace was patented by Charles A. Keller, of Paris, France, on December 17, 1901. The electrodes are trucks mounted on rails, and each adjustable toward a central horizontal fire brick hearth which carries the main body of the charge. The electrode carriages are framed in iron, covered by a fire brick arch which bears the carbon or outer surface of the electrode. The central horizontal hearth, and the upwardly inclined lateral electrodes together form a broad, shallow furnace bed, over which a layer of granular carbon is spread to serve as a circuit closer between the electrodes, and by its resistance

<sup>2</sup> *L'Electricita*, 20, 40, S. 627, 1901.

to develop a temperature sufficient for the reaction. Any resistance material may be substituted for this if the carbon should prove undesirable. For the production of chrome iron a bed of granular iron may be used which would alloy with the chrome as reduced. The furnace proper is inclosed within a fire brick vault to preserve the heat and exclude the air.

M. Armengand, Jr., of Paris, has secured by French Patent No. 301,804, of July 5, 1900, a process for the manufacture of mild ferrochromium in the electric furnace, which will contain Cr 60%, Fe 29 to 39%, and C 1%. The product is magnetic, tough, comparatively soft, and may be drilled by steel, characteristics which distinguish it from ordinary ferrochromium.

*Bichromates and Other Salts.*—Dr. Berthold Redlich, of Berlin, Germany, manufactures chrome yellow by electrolyzing lead hydroxide, which is obtained by exposing lead anodes to the action of an electric current, in a nitrate or acetate electrolyte. The resulting hydroxide precipitated from its solution by means of an alkali, reacts directly and in the cold on chromates or bichromates. The physical characteristics of the hydroxide may be transmitted to the product, and either a flocculent or crystalline chrome yellow produced by using a concentrated cold solution or a warm dilute solution. The alkali salts employed as electrolytes furnish the alkali used to precipitate the lead hydroxide. If no free acid be used in the subsequent chrome admixture, orange chrome is produced, free acid being necessarily present for the production of the lemon shades. The process is said to be much cheaper than the former practice.

A. Shearer, of Manchester, England, in the latter part of 1900 secured English Patent No. 14,021 for improvements in the manufacture of sodium and ammonium chromates.

#### CHEMISTRY.

*Review of Analytical Chemistry.*—(By Edmund H. Miller.)—J. Ferec<sup>1</sup> states that metallic chromium is readily deposited on a platinum cathode from a solution of crystalline chromic chloride acidified with hydrochloric acid, steel gray in color; while from a solution containing chromic and potassium chlorides in the proportion of  $\text{CrCl}_3$  to  $3\text{KCl}$ , it comes down as a silver white metal. The current used was 8 volts and 15 amperes per 100 sq. cm. of cathode area.

C. Reichard,<sup>2</sup> in an article on the recognition of chromic acid by hydrogen peroxide, calls attention to the following difficulties: (1) Vanadic acid exercises a remarkable influence on the perchromic acid reaction, by giving a brownish color which interferes with the clear blue of the perchromic acid. This is noticeable when the vanadium is present in the proportions of one part of ammonium metavanadate to 10 parts of potassium dichromate.

(2) That both arsenate and phosphate of sodium counteract the disturbing influence of vanadic acid on the reaction; while other salts, such as  $\text{NaNO}_3$ ,  $\text{NaNO}_2$ ,  $(\text{NH}_4)_2\text{S}_2\text{O}_8$ ,  $\text{KIO}_3$ ,  $\text{NO}_2(\text{NO}_3)_2$  have no influence.

(3) That molybdic and tungstic acids appear to influence the reaction similarly to vanadic acid.

<sup>1</sup> *Bulletin Société Chimique*, 25, 617.

<sup>2</sup> *Zeitschrift fuer Analytische Chemie*, 40, 577.

R. Hartmann\* describes an application of the ordinary volumetric method for chromium, by estimating the oxidizing power of the chromic acid, to the determination of chromium oxide in mordants. This method should prove most acceptable and is a valuable improvement to the tedious gravimetric methods which have been used. It is in brief as follows: About 1 g. of the chromic acetate (about 21°B.) is diluted with from 10 to 15 c.c. of water and a little strong caustic soda solution is added until the precipitate dissolves. The solution is heated on a water bath and sodium peroxide is added until the solution is yellow and the oxidation to sodium chromate complete; then evaporated to dryness to decompose any excess of peroxide, redissolved in 500 c.c. of water, and acidified with dilute sulphuric acid. 50 c.c. of N/10 solution of Mohr's salt ( $\text{FeSO}_4(\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$ ) are added and after diluting to a liter the excess of ferrous iron is titrated by N/10 potassium permanganate, to a dirty violet color. The chromium is calculated from the amount of Mohr's salt it oxidizes on the bases of  $1 \text{ Cr} = 3 \text{ Fe}$ .

## CLAY.

THE production of clay products in the United States during 1901 increased considerably over the output of the preceding year, the aggregate value being \$87,747,727, as compared with \$78,704,678 in 1900. The chief cause of the increased output was the great prosperity in the building trades, which is reflected in the very large increase in the production of building brick. The drain tile trade, however, suffered materially from the drought in the central West. At the beginning of the season the demand was so great that almost a brick famine resulted in many places, manufacturers frequently being compelled to refuse further orders. Despite the increased demand for bricks lower prices ruled, which resulted ultimately to the benefit of the trade, as thereby considerable competition was prevented, both for the present and for the future. The number of firms reporting brick and tile products during 1901 was 5,887.

The production of clay and clay materials in the United States is summarized in the following table:—

PRODUCTION OF BRICK AND CLAY WARES IN 1900 AND 1901.

| Kind.                                             | 1900.     |              |        | 1901.     |              |        |
|---------------------------------------------------|-----------|--------------|--------|-----------|--------------|--------|

| Sewer pipe and drain tile.....                    | .....     | e 8,350,000  | .....  | .....     | 6,735,969    | .....  |
| Crude clay, stoneware and misc. man'tres (c)..... | .....     | e 8,500,000  | .....  | .....     | 15,448,890   | .....  |
| Totals.....                                       | .....     | \$78,704,678 | .....  | .....     | \$87,747,727 | .....  |

(a) Not including silica brick. (b) Including terra cotta, hollow building tile or blocks, roofing tile, floor tile and all other clay building material. (c) Including the value of common stoneware and various miscellaneous clay manufactures and crude clay used in pottery, for laying fire brick, in paper making, as burnt clay railway ballast, for the manufacture of gas retorts, glass pots, zinc retorts, etc. (e) Estimated. (f) Included under crude clay, etc.

The collection of these statistics is attended with many difficulties. In no other branch of the mineral industry except that of stone is the number of producers so large and so widely distributed. Most of them operate on a small scale, and as but little outlay of time and capital is required to open a brickyard,

adoption is of no serious consideration. The list of producers consequently is subject to continuous revision. A further difficulty arises from the fact that some concerns do not keep any records of their work, and are therefore unable to furnish accurate reports.

The production of brick and clay building material by States in 1900 and 1901 is presented in the above tables, in which the columns "common brick" include only the ordinary red brick that is used generally in building. Under "fire brick" we have grouped pressed brick of all colors. Under "fire brick," only what is properly termed alumina brick is included. Such silica bricks, Dinas brick, which is also properly called "fire brick" or "refractory brick," being omitted, because it is not a clay product. "Other clay material" includes fancy or ornamental and enameled brick, roofing tile, terra cotta, terra mber, floor tile, hollow building blocks, etc. All the clay material other

(a) Included in "Other States." (b) Includes Hawaii. (c) Value of front brick for Wyoming included in other clay building material. (d) Includes all products made by less than three producers in one State, in order that the operations of individual establishments may not be disclosed. (e) Fancy and ornamental brick, stove linings, drain tile, ornamental terra cotta, fireproofing, ordinary tile, including adobe, assayers' supplies, boiler and locomotive tile and tank blocks, building blocks, burnt clay ballast, chemical brick, patent chimney brick, chimney pipe and tops, clay furnaces and retorts, conduit for underground wires, crucibles, cupola brick, fence posts and stubs, fire clay mortar, flue linings, frost-proof cellar brick, furnace mantles, gas logs and settings, glass-melting pots and glass-house furnace blocks, grave markers, hollow bricks, muffles, supports and slides, porous cups, runner brick, sidewalk tile, souvenirs, stone pumps, terra-cotta vases, vitrified sewer brick, wall coping, water pipe, and well brick and tile. (f) Partly included in "Other States."

than brick, which is now used so extensively in the construction of fireproof buildings is included under this classification. A slightly different classification has been adopted for 1901, which is fully explained in the individual headings of the columns and in the appended foot notes.

## OF THE PRODUCTS OF CLAY IN THE UNITED STATES IN 1900 AND 1901.

| State.                | 1900.           |              |              | 1901.           |              |               |

of the pottery products of Idaho and Montana is included with that of Colorado. (b) Value of products of Florida is included with that of Georgia. (c) Porcelain electrical supplies for Indiana New York. (d) Value of the pottery products of Maine is included with that of Massachusetts. (e) The pottery products of Wisconsin is included with that of Minnesota. (f) Value of pottery New Hampshire is included with that of New Jersey. (g) Includes porcelain electrical supplies and china for Ohio. (h) China for Ohio included in New York. (i) Included with Connecticut. (j) by Connecticut alone. (k) Included in Oregon. (m) Included in "Other States." (n) Includes Comprising pottery totals for the following States: Florida, Kansas, Maine, Montana, New Hampshire and Utah. This total could not be distributed among the States to which it belongs without the operations of individual establishments.

exponent of the increasing use of burned clay products as a building may be cited the number of building permits issued, together with the erected under these permits in 42 of the principal cities of the United for the past two years. In 1900 there were 68,417 permits affecting valued at \$241,516,585, as compared with 85,571 permits affecting valued at \$372,173,631 in 1901, an increase in number of 25% and 50% in value.

## FIRE CLAYS AND THEIR MANUFACTURE INTO REFRACTORY MATERIALS.

BY HEINRICH RIES.

*Raw Materials.*—The individual clays used in the manufacture of refractory goods show as much variation in their physical and chemical characters as those employed in the making of any other high-grade clay product, and the fact that a clay is used in making fire brick or other refractory ware does not necessarily mean that it is of refractory character; indeed some of the clays used are of a low order of refractoriness, but these are seldom added to the mixture in large quantities, being employed in small amounts because of some special physical character, such as high plasticity, or density after burning.

It would be almost impossible to give a definition of the name fire clay which would include everything that is put on the market, for many materials are called refractory which have very low fire-resisting qualities; but it seems desirable that the term should properly be restricted to include only those clays which are able to withstand a high temperature, although this character alone does not always adapt them to the manufacture of refractory wares. In the United States a standard of refractoriness has never been adopted, but a clay should not be considered refractory unless its fusing point lies above 2,700°F. The degree of plasticity, air-shrinkage, fire-shrinkage, texture and color, are exceedingly variable in clays of high refractoriness and consequently these physical properties cannot be specified in the definition.

*Color.*—Fire clays vary greatly in color, being frequently bluish gray, gray, or black, due to the presence of organic matter. The reason for this is that many fire-clay deposits are intimately associated with coal-beds, and derive their carbonaceous coloring material from the organic matter which accumulated in the swamps in which the coal-forming plants grew. Many refractory clays, however, do not contain this finely disseminated organic matter, and in these cases the color may be buff, white, yellowish, or pink, its shade and density varying with the amount and form of iron which the clay contains. Some of the New Jersey clays are mottled red and light buff, red and white, or yellow and white, owing to the fact that the iron oxide is not evenly distributed throughout the mass.

*Hardness.*—There is considerable variation in the hardness of clay due to the conditions under which it has been formed. Many of the Carboniferous fire clays buried under thousands of feet of other sediments have been transformed to shale by pressure, while others formed in more recent geological times, and covered since their formation by less sediment have not been hardened, but have retained their soft plastic condition and can be easily dug by pick and shovel. The Cretaceous and Tertiary fire clays in New Jersey and other portions of the Atlantic coastal region are of this class. The shale clays, although seemingly hard and non-moldable, will generally yield a plastic mass on being ground and mixed with water. For this reason shale fire clays and soft fire clays are grouped together, forming the "plastic" fire clays, to distinguish them from the "flint" clays, which are hard, dense, fine-grained, of variable color, sometimes very slight luster, and conchoidal fracture. The latter usually occur in beds, interstratified with other rocks similar in origin to the shale clays with which

they may sometimes occur in the same bed. On grinding and mixing with water fire clays develop little or no plasticity, even though they may approximate plastic clays in composition.

*Texture.*—The same differences in texture exist in refractory clays as in other grades; some are very coarse and sandy, showing large angular particles of quartz, while others are exceedingly fine and show little or no grit. This fineness may have more or less effect on the fusibility of the clay, as will be mentioned later.

*Fusibility and Composition.*—The refractoriness of a fire clay depends chiefly on the chemical composition and partly on the fineness of grain. Analysis shows that they contain the same components as other clays, but in slightly different proportions.

The percentage of fluxes, *i.e.*, ferric oxide, lime, magnesia and alkalies, is usually quite low, as is evident from the analyses of a number of different fire clays given in the subjoined table:—

| Specimens. | SiO <sub>2</sub> . | Al <sub>2</sub> O <sub>3</sub> . | Fe <sub>2</sub> O <sub>3</sub> . | CaO.   | MgO.   | Alkalies. | Moisture. | H <sub>2</sub> O.              | Miscellaneous.                                                                                         |

As can be seen from the above table, there is always a small percentage of fluxes, and in most cases the total quantity rarely exceeds 4 or 5%. Another point to be noted is the variation in the percentages of silica and alumina, some fire clays being highly siliceous, while others are very aluminous. The latter also show a high content of combined water. While it has usually been considered that a small quantity of fluxes added to a very refractory clay will tend to lower its refractoriness, it seems possible under certain conditions to add a large amount of some fluxing material without materially decreasing the refractoriness

of the clay. This is of special bearing in the case of highly siliceous mixtures, as shown by E. Cramer,<sup>1</sup> who was led to experiment by the fact that very highly siliceous rocks, as quartzite schist, when used as a lining in lime and cement kilns, were apparently free from any fluxing action although in contact with the kiln contents at a very high temperature. He experimented with artificial mixtures of carbonate of lime and sand or kaolin, and obtained the following results:—

| Fusing Point Seger Cones. | Chemical Composition. |                                  |                    |

These results show that the introduction of the kaolin lowered the fusing point appreciably.

The manner in which the flux is distributed in the clay must be considered in connection with its effect on refractoriness. If the fluxing material is finely distributed it will be more effective than if the same quantity were in larger grains here and there in the material. This variation in the distribution of the fluxing material is often seen in the case of iron, which, when evenly scattered through it, gives the clay a uniform tint and when present in small lumps shows spots of rust forming fused specks in burning. In the latter case the iron in the raw clay may be present as pyrite, commonly known to the workman as sulphur balls, which are readily recognized by their metallic luster and yellowish color; as limonite concretions often derived from the weathering of pyrite, or as siderite. Many fire clays contain from a few tenths to several per cent. of titanium, but its effect is seldom considered, as its fluxing action is of no moment when present in small quantities. Silica is regarded as a refractory constituent at low temperatures, and as a flux at high temperatures unless in excess.

Although the size of grain is considered by many to influence the fusibility of a clay, others<sup>2</sup> claim that the size of grain has nothing to do with the heat-resisting quality of the clay. The fusibility of several well-known American fire clays expressed in terms of Seger cones are given in the subjoined table, which includes for comparison several foreign clays:—

| Locality.                                      | Seger Cone Number. | Locality.                      | Seger Cone Number. |

*Plasticity and Tensile Strength.*—The plasticity of fire clays varies from

<sup>1</sup> *Thonindustrie Zeitung*, 25, 976.

<sup>2</sup> H. O. Hofman, *Transactions of the American Institute of Mining Engineers*, 1898, Vol. XXVIII., p. 440.

nothing in the flint clays to a high degree in many clays from New Jersey. This naturally means a variation in tensile strength, which may range from a few pounds per square inch in lean, sandy clays, to 200 lb. or more in very plastic ones.

*Air- and Fire-Shrinkage.*—The shrinkage of fire clays is often in close agreement with the degree of plasticity which they possess. As a rule fire-brick mixtures show a very low shrinkage as they contain much non-plastic material, but many of the ingredients are clays of high plasticity and consequently of high shrinkage and bonding power; it is on account of the last-mentioned quality that they are added for the purpose of holding the non-plastic elements together. All fire clays do not shrink in burning, and those of high silica content may expand slightly. In a series of tests by Cramer, pure silica or quartz, heated alone, increased in size from 3.1 up to 9.5%. The melting point was usually quite high and the swelling was found to increase continuously as the heating proceeded. Highly plastic fire clays often burn to a very dense body; the temperature at which this densification takes place, however, is not the same in all cases. Fire clays used in the manufacture of glass pots may become very dense at a temperature slightly above 2,000° F., while others may not show this same condition until they have been heated to at least 2,400 or 2,500° F.

*Occurrence.*—Fire clays occur under a variety of conditions. They are sometimes associated with beds of coal, or interbedded with sandstones, limestones, or other sedimentary rocks, or again in the form of a thick series of beds, all of which are more or less refractory in their character. It is a common custom among coal miners to apply the term fire clay to almost every underclay found associated with the coal seam, and while this term is a correct one in many regions in Pennsylvania or Indiana, it does not follow that every clay underlying a coal bed is refractory. In Michigan, the coal beds are invariably underlain by a bed of clay or shale, often of gray color and carrying plant remains. These are called fire clays, yet not one of them is refractory, as far as experience goes. Fire clays may often be interbedded with other plastic materials of a much less refractory nature. In some formations, as the Carboniferous, the clay deposits are often continuous over considerable areas while in others, as the Cretaceous beds of the coastal plain region, they frequently assume a lenticular form, thinning out horizontally, although of very great thickness in the central part of the mass. All fire clays are not sedimentary in origin, some being residual from the decomposition of feldspar veins.

The cause of the freedom of certain clay beds from fusible impurities has been explained in several ways. From the fact that many fire-clay beds underlie coal, it has been thought that the roots of the plants growing in the swamp under which the clay lay absorbed the alkalies and other bases from them. Against this may be pointed out that many clay beds of refractory character are not associated with deposits of plant remains. It has also been suggested that the leaching out of the fluxing impurities by surface waters purified the fire clays, but if this were true, the outcrops would be more refractory than the deeper or more buried parts of the bed—a condition not always present, and in some cases the reverse. It seems more probable that the fire-clay particles have come from the decomposition and erosion of rocks which were comparatively free from iron-

bearing minerals, and during the decomposition of the parent rock, many of the fluxing impurities were carried off in soluble form.

*Mining of Fire Clays.*—Two methods are usually adopted—the open pit or quarry method, and the drifting or underground method. The former is used where the clay outcrops at the surface and has little or no overburden. If the deposit is large and uniform throughout, the material can often be dug rapidly and economically with a steam shovel, but if the bed is small or the section involves a number of beds showing widely different characters, it generally becomes necessary to dig the material with pick and shovel, in order to avoid mixing the different varieties. The steam-shovel method of mining is applicable in some deposits in Ohio, while the open pit method is the one mostly used in other regions. Underground working is necessary where the fire clay is overlain by a considerable thickness of other material of no economic value. In some cases horizontal beds outcrop on the side of a hill or mountain, in which case it is customary to run a drift into the hill and drive radiating gangways from this. In other cases the shale bed has to be reached by means of a shaft from which levels are driven into the fire clay. In regions where this is necessary the refractory clays are often found interbedded with coal or other clays of considerable value. Many clays in Pennsylvania are worked by drift, while in Indiana and Missouri, the shaft method of mining is often adopted.

*Geological Distribution.*—Refractory clays are found in many formations from the pre-Cambrian to the Tertiary. The pre-Cambrian fire clays are of residual nature and rarely of great extent, being more or less veinlike in form. They occur at several points in the southern Appalachian region. There is no reason why residual fire clays should not be formed from igneous or metamorphic rocks of pre-Cambrian or other ages, but they are not known to exist in any quantity in the United States; in Germany, however, some of the more refractory clays are derived from the weathering of quartz porphyry. The Carboniferous is one of the most important American sources of plastic and the flint fire clays, and deposits are found in Pennsylvania, Ohio, Kentucky, Indiana, and Missouri. The Cretaceous contains vast supplies of fire clay in the Atlantic coastal plain region of the United States, which are especially abundant in New Jersey and are also known in Maryland, North Carolina, Georgia, Alabama, and Texas. The Jura-Trias contains no refractory materials in the Eastern States, but some of the fire clays found along the eastern Rocky Mountains belong undoubtedly to this age. Fire clays of Tertiary period are known in the Atlantic States, and also in the Cordilleran region, but as compared with those of the Cretaceous, they are very little developed. Up to the present time few refractory clays of Quaternary period have been developed in the United States. They are known in New Jersey.

*Geographical Distribution of Fire Clays in the United States.*—Many State surveys have taken up the investigation of their clay resources, and much information is to be obtained from these reports, but there are other States containing an abundant supply of refractory material which has never been systematically investigated, owing often to the absence of a State survey.

Alabama.<sup>3</sup>—Refractory and semi-refractory clays are found chiefly in the

---

<sup>3</sup> H. Ries, "The Clays of Alabama," Bulletin No. 6, *Alabama Geological Survey*.

etaceous formation, but are also known in the Carboniferous. The latter are found at Fort Payne and Valley Head. Some refractory clays are also seen in association with the bauxite deposits near Rock Run. The fire brick works atasley, near Birmingham, have drawn much of their raw material from Woodcock, Bibbville, and Anniston. It is not unlikely that the residual kaolins found in the areas of crystalline schists may be found of value for the manufacture of fire brick at some future time, but at present most of them are located some distance from the railroad.

Arkansas.<sup>4</sup>—Little has been published on the clays of this State, but an abundance of good material is said to occur in the Mesozoic formations.

Colorado.<sup>5</sup>—There are many important fire-clay beds of Cretaceous age occurring in the eastern foothills of the Rocky Mountains. The deposits usually dip at a high angle and are interbedded with sandstones of Dakota age. Some of the clays are of high refractoriness, and can be used in the manufacture of fire brick, crucibles and assayers' apparatus. They have been actively mined near Golden and at several other localities, and form the basis of an important local industry.

Delaware.—Fire clays of Cretaceous period are said to be worked to a small extent. Some of them are used in the manufacture of chemical stoneware.

Georgia.<sup>6</sup>—The Potomac formation contains many clays of a white or nearly white color and of considerable refractoriness. They are mined at several localities along the Fall line, notably around Griswoldsville, but are little used in the manufacture of fire brick.

Indiana.<sup>7</sup>—Many beds of fire clay are found in the Coal Measures, and occur interbedded with coal seams, as well as with other clays or shales of less purity. The beds are often quite persistent, being pierced at many localities by shafts.

Kansas.—So little clay of good quality is found in this State that all of that required by the zinc smelters has to be shipped in from other States.

Kentucky.<sup>8</sup>—Both plastic fire clays and flint clays have been found in the State, and while an abundance of material is reported, the deposits have not been exploited systematically. A number of analyses are given in the reports of the Kentucky Geological Survey, referred to below. The known deposits are of Carboniferous and Cretaceous age, and exist in the counties of Ballard, Bell, Boyd, Boyle, Callaway, Carter, Edmonson, Graves, Grayson, Fulton, Hickman, and Muhlenberg.

Maryland.<sup>9</sup>—This State contains three classes of fire clay, viz.: (1) Flint and shale clays of the Carboniferous period, which are worked at several points along Savage Mountain in Alleghany County and manufactured into the well-known Mount Savage fire brick. These clays occur also in Garrett County. (2) Potomac clays, forming lenticular deposits at many points in the coastal plain, and

worked more or less in Cecil County for the manufacture of stove brick. (3) Residual clays of pre-Cambrian period, found at several points near the western edge of the coastal plain, and used in the manufacture of fire brick and gas retorts.

Missouri.<sup>10</sup>—Plastic and flint fire clays are found in this State. The former are of Carboniferous period, and are extensively worked around St. Louis, where they are associated with coal seams. The fire clays may be Ordovician, Silurian, or Carboniferous period, and usually form basin-shaped deposits in limestone. They are not as refractory as the Pennsylvania ones.

New Jersey.<sup>11</sup>—The fire clays are found chiefly in the Cretaceous formation which extends across the State in a belt from five to eight miles wide, from Perth Amboy to Trenton. The section, which is several hundred feet thick, involves several beds of fire clay and fire sand of well marked stratigraphic position. The most important of these is the Woodbridge fire clay, which is extensively worked, and supplies many of the fire-brick factories in that region and in other States.

New York.<sup>12</sup>—Fire clays are found on Staten Island, near New York City, and used locally.

North Carolina.<sup>13</sup>—Fire clays of residual character resulting from the decomposition of granite veins exist in the western and southern part of the State.

Ohio.<sup>14</sup>—The fire clay deposits are practically co-extensive with those of coal. The sub-Carboniferous contains valuable deposits of flint clay, which is mined at several points in Hocking County, and several beds of fire clay are also found in the Carboniferous conglomerate. Other beds occur over the Sharon coal in the Massillon sandstone, and also under the Mercer limestone. The Kittanning clay and shale is the most important in the State and is the formation which yields the well-known Mineral Point fire clay.

Pennsylvania.<sup>15</sup>—The refractory clays and shales of the coal measures of Pennsylvania form one of its most important mineral resources, especially in the western part of the State. Among the more important of these are the Bolivar fire clay, under the Freeport upper Coal Measures, and a fire clay underlying the Kittanning coal in Beaver County, etc. Another important bed occurs in Indiana, Cambria, and Beaver counties.

South Dakota.—Extensive beds of fire clay occur in the Dakota formation surrounding the Black Hills, and beds of good quality have been worked at Rapid City.

Tennessee.<sup>16</sup>—The clay resources of this State are similar to those of Kentucky. The Carboniferous fire clays are abundant in the eastern half of the State.

**Texas.**—Fire clays occur in the Fayette formation of the timber belt lands, and are known in Fayette, Henderson and Limestone counties.

**Uses of Refractory Clays.**—Fire bricks represent the most common type of refractory material and the greater part of the refractory clay which is mined is used for this purpose. The bricks are used for lining various types of metallurgical furnaces, brick kilns, lime kilns, glass furnaces, and in other places where resistance to great heat is required. With such a varied use it follows that the product must meet many different requirements. The first demand is for a great variety of shapes in order to fit into the outlines of the furnace or other structure in which they are to be used. For this reason many manufacturers have to carry a large number of stock shapes and many special ones. Next in importance to the shape is the condition under which the brick is to be used. Some simply require a resistance to heat, others must withstand abrasion, while others are exposed to the corrosive action of molten materials. From this it is evident that the manufacturer must produce not only a variety of shapes, but also must use a number of different mixtures, each compounded to suit special requirements.

Fire bricks are sometimes made from clay alone, or from a mixture of a small proportion of clay with other refractory materials. Of this class is the "Dinas" brick, which contains about 97%  $\text{SiO}_2$ , and about 3% of some bonding material, as lime ganister, which is a refractory siliceous rock containing enough clayey matter to hold it together when wet, and magnesite brick, made of magnesium carbonate, or magnesite, with a clay binder. Among special kinds of refractory materials are locomotive tile, steamboat tile, steel runners, sleeves, nozzles, crucibles, stove-linings, glass pots, gas retorts tuyeres, rolling-mill tiles, hexagon stove shapes, grate-backs, glass tank furnace blocks, muffle furnaces, muffles, scorifiers, and various other special shapes.

**The Manufacture of Fire Brick.**—Fire brick are usually made of a mixture of several more or less refractory clays, ground fire brick or burned clay, and sand, which is of good refractoriness and burns to a brick of the proper physical character. If the product is to stand heat alone and change of temperature, it is usually made of rather open texture, but if resistance to corrosive action is called for, a more dense-burning body must be made by the addition to the mixture of a greater body of plastic clay. Shale must first be ground in a dry-pan, and old fire brick, which are added as anti-shrinkage ingredients, are generally ground in the same machine.

**Mixing the Clays.**—Clays are mixed in soak pits, ring pits, or wet pans. The first-named consists of a large and rather shallow pit into which are dumped the ingredients of the brick mixture one layer on top of the other, each in the right proportion. When the pit is filled, water is added and the mass allowed to soak thoroughly, after which it may be further mixed in a pug-mill before molding. The ring pit method is the same as that used in the manufacture of soft-mud building brick, the proper quantity of the different clays, sands, and ground up bricks being dumped into the pit, water added, and the mass thoroughly mixed and tempered by means of the large iron wheel which travels around in the pit.

When wet pans are used the material is tempered very rapidly, and in some

cases the harder lumps are given a preliminary grinding in a dry pan. After the mixture has been thoroughly worked or tempered it may be carried directly to the molding floors, or, if not required for immediate use, it is stacked up in bins and covered with cloths to prevent the evaporation of moisture as much as possible.

*Molding.*—Fire brick manufacturers originally molded ordinary shapes of fire brick by the soft-mud process, and, while some of them a few years ago tried the stiff-mud, or the dry-press process, the conclusion has been reached that the soft-mud method of molding is the best. In molding soft-mud fire brick some works form the common shapes by hand-pressure in wooden molds, while others prefer the soft-mud brick machine, operated by steam power. The stiff-mud process is sometimes used and in rare instances the semi-dry process. The product in either case is a very soft green brick of rather rough shape, which has to be re-pressed, usually in a hand-power machine. The re-pressing makes the brick somewhat denser, and straightens the edges and corners.

*Drying and Burning.*—Drying is usually done on floors heated by flues passing underneath from a coal fire at one end.

Burning was formerly done in up-draft or down-draft kilns, but at the present most manufacturers use a circular down-draft kiln of diameter varying from 15 to 25 ft. In the case of fire brick less skill is required for successful burning than in most other branches of the clay-working industry. Color is not an item that has to be considered, and, on account of the refractory nature of the clay, there is no danger of overburning, for the temperature of fusion of the brick is never attained in the kiln. Some of the brick may come from the kiln softer than others, but this does not mean a loss, as many prefer a soft brick to a hard one. The temperature attained in most fire-brick kilns probably never exceeds 2,400° F. The forming of large or complicated shapes of fire brick, such as slabs, tiles, or other pieces, cannot be done by machinery. These are usually shaped by hand in wooden molds, often filled with more clay than necessary, and set into a machine. On applying pressure on the top of the clay, the excess is squeezed out and scraped off, the mold is then emptied on to the drying floor or to a wooden pallet and subsequently carried to the drying-room.

Fire bricks are not subjected to as much heat in drying as other bricks, and Eastern manufacturers usually dry them at a higher temperature than those in the West.

*Gas Retorts.*—The manufacture of gas retorts represents a branch of the refractory ware industry which is of decreasing importance. In making these retorts, large sectional wooden molds are used, the retort being built on end. The mold consists of an outer shell and a wooden core, whose surface is the same as the interior surface of the retort. The lower section of the mold is set on the planking on which the retort is to be built up, and the first section of the core placed inside of it, the space between the two being tamped full of clay. Then a second section of the mold is set on the first, and the clay filled in until the entire length of the retort is built up. When completed, the core is withdrawn and the shell of the mold removed. The retort remains standing on end and is carefully dried for several weeks before being placed in the kiln for burning.

**Glass Pots.**—The manufacture of glass pots represents probably the highest branch of the refractory clay industry, as it requires not only the best grades of clay, but also great skill and care during the entire process of manufacture. Furthermore, the product is one of the very few forms of refractory material which is not burned before use. For many years the glass-pot clays used in the United States were imported, mainly from Germany and Belgium, but at present, although the imports have not entirely ceased, much native clay is used. The requirements of a glass-pot clay are most severe, for in use the pots are not only subjected to high temperature, but also to the corrosive action of powerful fluxes, as soda or lead. The raw material must therefore be refractory, in order to resist the fluxing action of the molten glass; it must be plastic to a marked degree in order to bind the mass together, especially as more or less non-plastic material is put into the mixture and the pot in the green condition has to hold together when moved, and finally it must have a proper density when burned at a low temperature.

The American glass-pot clays are obtained chiefly from Missouri and Pennsylvania, although small quantities are mined in Ohio. Some clays are washed before use and all raw materials are rigidly examined, to insure proper quality.

Homogeneity is of great importance, and the miners of the clay often allow it to weather from several months to two years or more before it is used. The mixture is carefully ground, tempered, and stored under moist blankets until used. The pot is built up piece by piece, using special clays in the top, sides and bottom, depending on the action to which each will be subjected.

From one month to six weeks may be required to complete a pot, and several additional weeks for drying. The pot is then sent to the glass factory, where it is put into the furnace and heated up very slowly. It is not allowed to cool until it is worn out, which may be several months. The tank furnaces used in the manufacture of glass are lined with large tightly-fitting blocks of refractory material similar in composition to that used in making the glass pots.

#### REVIEW OF LITERATURE OF CLAYS AND CLAY PRODUCTS FOR 1901.

BY HEINRICH RIES.

##### CLAY DEPOSITS.

**UNITED STATES.—Colorado.**—The Colorado clay deposits are described by S. Geijsbeck in the *Clayworker*, Vol. 36, p. 424, dwelling chiefly on the Mesozoic fire clays occurring along the eastern foothills of the Rocky Mountains.

**Iowa.**—In the *Eleventh Report of the Iowa Geological Survey* the clays are referred to under the special reports on Louisa, Marion, Pottawattomie, Cedar, Page, Clay and O'Brien counties.

**Wisconsin.**—The clays and clay industries of Wisconsin are treated by E. R. Buckley, in the *Report of the Wisconsin Geological and Natural History Survey* (Bulletin No. 8, Part I., Economic Series, No. 4). The State contains a variety of clays suitable for the manufacture of brick and tile. The residual clays are derived from both igneous and sedimentary rocks, while the transported clays are of glacial Lacustrine or Æolian origin. The clays of the extreme northern,

eastern and southern parts of the State are very calcareous; those found in the southwestern, western, and northern central portions are moderately so, while in the central section, which borders the area of crystalline rocks, they are very low in calcium. White-burning sedimentary clays occur in the western and central portions of the State, and some are washed and prepared for paper manufacturers.

**FOREIGN COUNTRIES.**—*Austria.*—F. Ulzer, in the *Mittheilung des k. k. Thon. Gewerbe Museum*, in Wien, 1900, 10, 190-191, describes a washed kaolin which had 2.95%  $\text{Fe}_2\text{O}_3$  and in burning became yellow at  $1,270^\circ\text{C}$ . The locality is not given.

*British Guiana.*—In the *Engineering and Mining Journal*, August 17, 1901, the existence of a superior grade of kaolin is reported from the district along the Corentine River in British Guiana. The analysis of this kaolin is:  $\text{H}_2\text{O}$ , 8.01%;  $\text{TiO}_2$ , trace;  $\text{Fe}_2\text{O}_3$ , 1.21%;  $\text{Al}_2\text{O}_3$ , 24.16%;  $\text{CaO}$ , 0.39%;  $\text{MgO}$ , 0.27%; potash, 0.04%; soda, 0.01%; sand, 23.35%;  $\text{SiO}_2$ , 41.98%.

*Germany.*—Kaolin from Hirscham, Germany, as stated by the *Thonindustrie Zeitung*, Vol. 25, p. 2005, showed  $\text{SiO}_2$ , 47.84%;  $\text{Al}_2\text{O}_3$ , 38.19%;  $\text{Fe}_2\text{O}_3$ , 0.7%;  $\text{CaO}$ , 0.65%;  $\text{MgO}$ , trace;  $\text{K}_2\text{O}$  and  $\text{Na}_2\text{O}$ , 0.66%.

*Italy.*—Some of the china clay used in Italian industry is obtained from domestic sources, yet the larger quantity comes from England and France, whose products are superior. Many veins of kaolin are reported to exist in Sardinia, according to the *Journal of the Society of Chemical Industry*, December, 1901, p. 1259. The kaolin pits of the Province of Vicenza, Italy, have been worked for a number of years. The deposit lies along the contact of the Triassic limestone and porphyritic tuff, but the percentage of iron in it is sufficient to prevent its use for porcelain. (*Thonindustrie Zeitung*, Vol. 25, p. 1034.)

*New South Wales.*—According to the *Report of the Department of Mines of New South Wales* for 1900, fire clay is mined to some extent. Several analyses are given for different localities, one of which, from Newbridge, shows 0.08% V. The clays of New South Wales are referred to and many analyses given in the volume on the *Mineral Resources of New South Wales* for 1901.

*Ontario.*—Analyses of clay from Marl Bank and East Garafraxa, Ontario, are given in the *Report of the Bureau of Mines*, 1901, p. 16. These clays are used for making Portland cement.

#### CLAY INDUSTRIES.

*Pennsylvania.*—W. G. Irwin, in an article in the *American Manufacturer*, 1901, p. 886, on fire clays and the fire-clay industry, makes general reference to some of the better known fire clays of Pennsylvania. The same author, in a paper on the silica brick industry, *Ibid.*, p. 950, refers to the manufacture of these products in Pennsylvania. The plant of the Soisson Fire-Brick Co., at Connells-ville, is described on p. 762 in the issue of June 20, 1901, and analyses of the raw material are given.

*Formosa.*—According to the *Engineering and Mining Journal*, Vol. 72, p. 64, the brick-making industry in Formosa is said to be growing, especially as a result of recent encouragement received from the Japanese, who suggested the use of

kilns for burning bricks. There are now 12 large and prominent factories in which Japanese are interested, which have a total monthly production of 1,500,000 bricks. Roofing and floor tiles are among other clay products.

*France.*—The clays and clay products at the Paris Exposition of 1900 are described by H. Ries in the *Twenty-first Annual Report of the United States Geological Survey*, Part VI., continued.

*Germany.*—G. C. Vater describes, in the *Clayworker*, July, 1901, p. 20, the clay mines and works at Gross Almerode, Germany. The clays are used to a large extent in the manufacture of glass pots and shipped to many foreign countries. A large amount of the clay which is of Tertiary age is mined underground.

*Philippines.*—G. B. Rice, in the *Clayworker*, p. 385, describes the manufacture of fire bricks in the Philippines. The refractory clay occurs from 25 to 50 ft. below the surface. The molding is done in molds of hard wood and the bricks are baked in rather crude kilns.

*Russia.*—The ceramic industry of Russia is briefly referred to in the *Thonindustrie Zeitung*, Vol. 25, p. 1875.

*Scandinavia.*—The brick industry of Scandinavia is briefly discussed in an anonymous article in the *Thonindustrie Zeitung*, Vol. 25, p. 1302; also another article which also includes Denmark, in the same volume, p. 1350.

*South Africa.*—Brick-making in South Africa is referred to in the *Clayworker*, Vol. 36, p. 219.

*United Kingdom.*—Hecht and Gary, in the *Thonindustrie Zeitung*, Nos. 72 and 73, describe the clay products at the International Building Exposition, held in London.

#### REFRACTORY MATERIALS.

E. Cramer, in the *Thonindustrie Zeitung*, 1901, Vol. 25, p. 864, gives the results of his examinations of a number of substances used in the manufacture of Dinas bricks and the effect on them of repeated heating. He found great differences in their behavior, especially as regards their density, bulk, and expansion. After eight heatings at cone 16 to 17 the sp. gr. of quartz varied from 2.45 to 2.66. On the first heating there was a very irregular increase in bulk in the different heatings; one specimen of a fusion point the same as cone 36 increased 3.1%, and another of a fusion point cone 35 increased 9.5%. The purest materials seemed to swell only a little at first, later the gain was continuous. The same author, in experimenting on the softening point of refractory clays, as given in the *Thonindustrie Zeitung*, Vol. 25, p. 706, made cylinders of these materials and heated them several times to cone 17, the bars being supported only at the ends. He came to the conclusion that clays became more refractory the oftener they are fired.

Dr. Steger, in the *Thonindustrie Zeitung*, Vol. 25, pp. 1918, 1934, 1956, discusses the different kinds of refractory materials, including magnesia bricks, chromite bricks, lime bricks, carborundum, and refractory tiles. Numerous analyses are given of the raw material obtained from different localities.

The fusing points of a number of quartzites from southern Russia are given

in the *Thonindustrie Zeitung*, Vol. 25, p. 1850. Most of them melt around cone 34, and they increase in size during the heating from 1·2 to 6%.

Silica brick is manufactured to a large extent in western Pennsylvania, much of it being made from sandstone of Medina age (*Clayworker*, Vol. 36, p. 130). The material is abundant in Huntingdon and Blair counties, while ganister deposits are also known.

During the past year an extensive find of flint fire clay has been made at Cowansville, Armstrong County, Pa. It lies in the upper Freeport stratum of the lower Coal Measures.

The manufacture of fire brick is discussed in the *Clayworker*, Vol. 36, p. 314.

#### PROPERTIES OF CLAY.

*Tensile Strength.*—I. A. Williams, in the *Clayworker*, Vol. 19, p. 11, discusses the tensile strength of dried clay as a measure of plasticity, and from the results of his tests on a series of Iowa clays, comes to the conclusion that unqualified reliance cannot be placed on the tensile strength of the dry clay as a measure of its plasticity, but that such tests serve as a means of comparison among clays of the same class.

According to E. Orton, Jr., in the *Transactions of the American Ceramic Society*, Vol. 3, p. 204, the tensile strength of mixtures of plastic ball clay with equal quantities of non-plastic sands will vary inversely with the diameter of the grain of sand, from grains of 0·04-in. diameter down to the finest grains obtainable, and furthermore the non-plastic ingredients of the clay influence the tensile strength inversely as the diameter of their grain, the finer-grained clays, other things being equal, possessing the greatest tensile strength.

*Composition.*—The analyses of several Southern clays lead W. H. Zimmer to believe that some kaolins contain hydrated silicic acid, the action of which is very noticeable on the pottery body. As stated in the *Transactions of the American Ceramic Society*, Vol. 3, p. 25, he finds that the presence of any important quantity of free hydrated silicic acid shows the following tendencies: (1) To produce, at equal temperatures, an increase in translucency over that obtained with quartzitic silica only; (2) to produce a better color; (3) to increase air-shrinkage and fire-shrinkage; (4) to lower temperature of vitrification; (5) to warp in drying; (6) to yield a hard coating which often forms on the surface from the deposition of  $H_2SiO_3$  from water used in making the ware plastic.

Dr. Carl Bischof, in a pamphlet entitled *Gesammelte Analysen der in der Thonindustrie benutzten Mineralien*, has collected in convenient form nearly all of the published analyses of foreign clays as well as many of American origin; analyses of refractory materials, other than clay, are also included.

*Bricks.*—A. Marston, in a paper in the *Iowa Engineer*, gives the results of a series of experiments on dry-pressed brick as compared with those from surrounding States. The tests included cross-breaking, crushing, absorption, specific gravity, and freezing. The author considers that the cross-breaking tests are of special value. In the absorption tests the brick showed a con-

siderable increase in weight in the first three or four hours, but after the first 24 hours the increase was extremely slight.

**FIREPROOFING.**—Mäckler, in the *Thonindustrie Zeitung*, Vol. 25, p. 2068, describes the form of fireproofing blocks known as Hourdis, so much used in southern Germany and Italy. They stand in strong contrast to American ones, having a thickness of only 10 mm. with a length of 100 cm. Attempts were made to manufacture these from calcareous clays of northern Germany without success. The analysis of the clay used was: ignition loss, 1.02%;  $\text{SiO}_2$ , 55.48%;  $\text{Al}_2\text{O}_3$ , 15.16%;  $\text{CaO}$ , 11.68%;  $\text{MgO}$ , 5.22%; alkali, 3.70%.

**CLAY BALLAST.**—W. Shea, in a paper before the Railway Road-Masters' Convention, in Washington, reported in the *Clayworker*, Vol. 19, p. 177, gives the cost per yard of ballast on the cars as follows: Land interest on track material, track labor, and stripping, 4c.; coal, 13.5c.; burning, 17.5c.; hand-loading, 7c.; total, 42c. He considers clay ballast very efficient but not as strong as screened rock ballast, although cheaper to maintain and easier on the rolling stock. The life of the two materials is considered to be about the same, but the life of the railroad tie is about 10% longer on clay ballast. The Chicago and Great Western Railroad is installing a large plant at Des Moines, Ia., for the burning of clay and shale to be used as ballast.

**PAVING-BRICK.**—The committee appointed by the National Brick-Makers' Association for determining the best methods of testing paving brick has handed in its final report, and according to the *Clayworker*, Vol. 36, p. 436, has adopted the following specifications for a standard method of conducting the rattler test:—

I. Dimensions of the Machine.—The standard machine shall be 28 in. in diameter and 20 in. in length, measured inside the rattling chamber. Other machines may be used, varying the diameter between 26 and 30 in., and in length from 18 to 24 in., but if this is done, record of it must be attached to the official report. Long rattlers must be cut up into sections of suitable length by the insertion of an iron diaphragm at the proper point.

II. Construction of the Machine.—The barrel may be driven by trunnions at one or both ends, or by rollers underneath, but in no case shall a shaft pass through the rattler chamber. The cross-section of the barrel shall be a regular polygon, having 14 sides. The heads shall be composed of gray cast iron, not chilled nor case-hardened. The staves shall preferably be composed of steel plates, as cast iron wears and ultimately breaks under the wearing action on the inside. There shall be a space of 0.25 in. between the staves for the escape of dust and small waste pieces.

Other machines may be used having from 12 to 16 staves, with openings from 0.125 to 0.375 in. between staves, but if this is done a record of it must be attached to the official report of the test.

III. Composition of the Charge.—All tests must be executed on charges containing but one make of paving material at a time. The charge shall be composed of the bricks to be tested and iron abrasive material. The brick charge shall consist of that number of whole bricks or blocks whose combined volume most nearly amounts to 1,000 cu. in., or 8% of the cubic content of the rattling

chamber. (9, 10, or 11 bricks are required for the ordinary sizes on the market.) The abrasive charge shall consist of 300 lb. of shot made of ordinary machinery cast iron, of two sizes, as described below, and the shot charge shall be composed of 75 lb. of the larger size and 225 lb. of the smaller size.

IV. Size of the Shot.—The larger size shall weigh about 7.5 lb. and be about 2.5 in. square and 4.5 in. long, with slightly rounded edges. The smaller size shall be 1.5-in. cubes, weighing about 0.875 lb. each, with square corners and edges. The individual shot shall be replaced by new ones when they have lost 10% of their original weight.

V. Revolutions of the Charge.—The number of revolutions of the standard test shall be 1,800 and the speed of the rotation shall not fall below 28 nor exceed 30 per minute. The belt power shall be sufficient to rotate the rattler at the same speed whether charged or empty.

VI. Condition of the Charge.—The bricks composing a charge shall be thoroughly dried before making the test.

VII. Calculating the Results.—The loss shall be calculated in percentages of the weight of the dry brick composing the charge, and no result shall be considered as official unless it is the average of two distinct and complete tests, made on separate charges of brick.

#### POTTERY.

*History.*—In an article in the *Thonindustrie Zeitung*, Vol. 25, p. 1368, the manufacture of Delft ware is said to have been commenced at Delft by Hermann Peters, in the beginning of the seventeenth century. By 1620 eight factories were in operation, and in 1670, 28 were running.

C. F. Binns, in the *Transactions of the American Ceramic Society*, Vol. 3, discusses the birth of English porcelain, and states that it really had its beginning in 1744. The composition of different materials used in its manufacture is also given.

R. L. Cawood, in the *Clayworker*, Vol. 37, p. 60, gives an interesting account of the evolution of the pottery industry of the United States, and points out the wonderful strides which the industry has made during the past 25 years.

The history of the Aachen pottery works is given in the *Thonindustrie Zeitung*, Vol. 25, pp. 77-78.

*Pottery Mixtures.*—E. Lindner, in the *Sprechsaal*, 1901, pp. 34-36, discusses porcelain sands and the composition of porcelain pastes. The composition of a porcelain body must be such that it will not only withstand temperature changes but also be plastic and transparent, the latter property varying with the temperature of the firing. Silica varies from 58 to 72%;  $\text{Al}_2\text{O}_3$ , 22 to 35%, and  $\text{K}_2\text{O}$  not above 5%. The calcining of flint before putting it into the body decreases breakage in firing. He also states that the most perfect porcelains are those in which the silica is completely combined with the alkali. Lime tends to increase the warping, but is sometimes used as a flux. Sandy pastes if not burned to vitrification may show great indifference to changes in temperature.

S. G. Burt, in a paper on the "Fineness of Flint and its Relation to the Manufacture of Pottery Bodies," in the *Transactions of the American Ceramic*

*Society*, Vol. 3, p. 17, discusses whether there is any difference in the effect produced by the use of French flint, silica sand, or rock flint, in pottery bodies and concludes that the difference, if any, is extremely slight, and that with uniform fineness of grain equally good results can be obtained by the use of any of those three kinds of flint, but that the variation in the degree of fineness may cause considerable variation in the behavior of the glaze.

*Glazes.*—In a report made to the Home Secretary on the "Use of Lead in the Manufacture of Pottery," by J. E. Thorpe, noted in the abstracts of the *Journal of the Society of Chemical Industry*, May, 1901, p. 475, the author comes to the conclusions that the lead in glazes is insoluble in a 0.25% HCl solution provided the ratio of bases to acids does not exceed 1.45:1.00. Finer grinding increases the solubility of the lead, still it was not as much as was expected. Most glazes when ground sufficiently fine for commercial purposes were found to be within the limits of insolubility prescribed for. It was also found that the insolubility of the lead does not depend on the actual quantity of this metal in the glaze.

In discussing the permissible variation in the silica and alumina content of raw lead glazes, W. M. Fickes, in the *Transactions of the American Ceramic Society*, Vol. 3, p. 112, finds that good, perfect glazes can be produced with other oxygen ratios than 1:2, but that ratios between 1:1.5 and 1:2 are the safest limits for raw lead glazes. The molecular ratio seems to exercise an important function in controlling the hardness of the glazes and the tendency to crystallization during cooling; between the molecular ratios of 1:8 and 1:15 there is more chance to form a good perfect glaze regardless of the oxygen ratios and RO elements than with other numbers, for each combination in which good glazes can be produced will depend on the fluxing power.

Under the heading of "New Glaze Fluxes," W. Cannon (*Ibid.* Vol. 3, p. 113) states that dolomite can be successfully used in place of whiting in many glazes, the results being the production of a better color and lack of crazing than any corresponding white glazes. He points out the abundance of dolomitic limestone, especially in Ohio, and believes that it can be used to replace the English whiting, which is much more expensive.

The ceramic stoneware made by the Sever's Porcelain works for the Paris Exposition is described by G. Vogt, in *La Ceramique*, 3 (133), 127-131; (abstracted in the *Journal of the Chemical Society of Indiana*, June, 1901, p. 500). Mr. Vogt describes the manufacture of this material and gives the composition of the glazes and the proportions of the different clays used.

Improvements in the bodies of stoneware and the increasing use of this material for chemical work is pointed out by C. Schatler, in the *Zeitschrift für Angewandte Chemie*, 1901, pp. 728-733.

H. Haskovec gives the following analysis of sand used for the manufacture of silica balls:  $\text{SiO}_2$ , 98.54%;  $\text{Al}_2\text{O}_3$ , 0.15%;  $\text{Fe}_2\text{O}_3$ , 0.32%;  $\text{MgO}$ , 0.03%;  $\text{CaO}$ , 0.01%; alkali, trace; ignition loss, 0.22%. This silica is considered to represent the composition he adopted for use in glazes.

J. Salt, in a paper on the "Flow of Underglaze Colors in Pottery," in the *Moniteur Ceramique*, Vol. 32, p. 138, points out that the "flowing of these printed

colors (chiefly blue, black, and dark green) of the underglaze when fired is produced by the aid of copper oxide added to the colors themselves or in some case by putting a mixture of lime and common salt in saggers with the printed ware. Similar results may be obtained by the presence of tin compounds and salt in the coloring glaze."

**PYROMETERS.**—A. F. Hottinger, after experimenting with Seger cones, concluded that "in the Cramer cones, which use a boro-silicate fritt, the oxide of iron should be dropped out because it introduces an element of uncertainty, but that this substance is not in itself the cause of irregular behavior of the Cramer cones when used in muffle terra cotta kilns," the real causes being due to the expulsion of boric acid from the cones by sulphuric acid generated in the fuel and also in the conversion of calcium carbonate into calcium sulphate in the same manner. As a result of these two changes the ratio of fluxing ingredients is greatly interfered with, so that a cone no longer melts at the proper temperature, or even melts in a normal manner when it finally does go over. He therefore recommends the use of another fritt which will not be so readily acted upon by acid vapors. He further says that little or no free lime should be used in the construction of the Cramer cone series.

**Bibliography.**—The following manuals and general works have appeared during 1901:—

Auscher, E., and Quilliard, C.—*Les Industries Ceramique*. J. B. Baillier et fils, Paris, 1901, 5 francs.

Beck, J.—*Ziegelei anlagen und Ziegel Fabrikation*. Stralitz, 1901. M. Hitzenkoferm, 6 marks.

Bischof, C.—*Gesammelte analysen der in der Thonindustrie benutzten Mineralien und der daraus Hergestellten Fabrikate*. Leipzig, 1901, 8 marks. In this the author has quoted a very large number of clay analyses from Europe and other parts of the world.

Graesse-Jaenneisac.—*Guide de l'Amateur de Porcelaines et de Fayance*. 9th edition, Dresden, 1901. G. Schonfeld, 8 marks.

Grimm, H.—*Die Fabrikation des Feldspath Porzelans*. Leipzig, 1901. A. Hartleben.

Fairie, J.—*Notes on Pottery Clays: The Distribution, Properties, Uses and Analyses of Ball Clays, China Clays and China Stone*. London. Scott, Greenwood & Co., 1901.

Le Fevre, L.—*La Ceramique dans ses Batiment*. Paris. Masson et Cie.

Loser, C.—*Handbüch der Keramische Industrie fuer studierende under praktiker*. Halle, 1901. L. Hofstetter, 4.50 marks.

Wildner, P. and Zimmerman, R.—*Die Thonwaren Industrie*, Berlin, 1901.

## COAL AND COKE.

great industrial prosperity of the United States during 1901, resulted in increased demand for, and supply of, coal during the year, the production of the enormous figure of 293,298,516 short tons (266,078,668 metric tons), compared with 268,315,433 short tons (243,414,163 metric tons) during 1900. Consumption of coal in the United States during 1901 was 260,509,235 tons, against 237,289,307 metric tons in 1900. The total production of all countries in the world during 1900 was 765,158,161 metric tons, against 693,937 metric tons in 1899.

| 1900..... | 239,587,351 | 1,909,376 | 241,476,727   | 7,917,519 | 6,740    | 233,552,463  | 237,239,307  |
| 1901..... | 261,573,675 | 1,920,248 | 263,793,923   | 7,883,393 | 3,808    | 256,406,727  | 260,509,236  |

*Ohio.*—The production of coal increased very slightly during 1901, the figures being 20,943,807 for that year, against 20,671,254 for 1900.

*Pennsylvania.*—The production in 1901 amounted to 82,305,946 short tons of bituminous coal and 67,471,667 short tons of anthracite coal, as compared with 79,318,362 short tons of bituminous and 57,363,396 short tons of anthracite coal for 1900. The output of anthracite in 1900 being much restricted by the strike of that year.

*West Virginia.*—The production of coal for 1901 was 24,068,402 short tons, against 21,153,340 short tons for 1900. Very little of the coal mined in West Virginia is consumed within its borders. The use of mining machines is increasing rapidly in the mines of the State.

*Other States.*—All of the coal mining States, excepting California, New Mexico and Tennessee, made increases in the output of coal during 1901. The three States enumerated above made very slight decreases, which may be noted by reference to the table at the beginning of this subject.

*Exports and Imports.*—There was a slight decrease in the exports of coal during 1901, the figures being 7,883,393 tons for 1901, against 7,917,519 tons in 1900. The imports increased slightly from 1,909,258 tons in 1900, to 1,919,962 tons in 1901. Both imports and exports are given in the subjoined table:—

## UNITED STATES EXPORTS AND IMPORTS OF COAL CLASSIFIED AS TO COUNTRIES.

The diagrammatic chart given on page 129 illustrates clearly the relative positions of the different coal producing countries and shows that the United States continues to be the greatest coal producing country in the world—a position it bids fair to occupy for many years to come.

#### PRODUCTION OF COAL IN THE CHIEF COUNTRIES OF THE WORLD.

The total production of coal in the world during 1900 was 765,158,161 metric tons, against 724,772,937 metric tons in 1899, an increase of 40,385,224 metric tons during the year.\* Detailed statistics may be found in the subjoined table:—

#### COAL PRODUCTION OF THE CHIEF COUNTRIES OF THE WORLD. (IN METRIC TONS.)

| Year. | Africa.   | Australasia.     |              |             |           |           | Austria-Hungary | Belgium.   | Canada.                         |                            | France.    | Germany.    |

(a) Includes estimate of 50,000 tons as the output of the Orange Free State and Transvaal, for which no statistics are available. (e) Estimated. (f) 1900 production estimated. (g) Not including lignite.

*Canada.*—The production of coal in Canada during 1901 was 6,186,286 long tons, valued at \$14,671,122, against 5,608,666 long tons, valued at \$13,290,429 for 1900, an increase of 577,620 long tons and \$1,380,693 in value for the year. The production of coke showed more considerable progress, being 373,625 long tons, valued at \$1,264,360 for 1901, against 157,134 long tons, valued at \$649,140 for 1900, an increase of 216,491 long tons and \$615,220 in value. The exports of coal during 1901 were valued at \$5,307,060, against \$4,599,602 during 1900, while coke exports for 1901 were \$192,910, against \$33,770 for 1900, a very considerable increase for the year. The imports of all kinds of coal during 1901 were 414,432 long tons, valued at \$275,559, against 330,174 long tons, valued at \$98,349 for the previous year. The imports of coke during 1901 were 308,786 long tons, valued at \$680,138. The total consumption of coal in Canada during 1901 was 9,718,272 long tons, against 7,932,267 long tons consumed in 1900. The coal fields about Cape Breton, Nova Scotia, continued to furnish the bulk of the production of coal, although British Columbia, New Brunswick, Manitoba and the other territories materially increased their outputs. The anthracite coal measures which range from 3 to 6 ft. in thickness on Queen Charlotte's Island, appear to be of very good quality, and compare favorably with Pennsylvania anthracite. The coal areas of Canada are estimated at 97,200 square miles, excluding areas known but undeveloped.

The Crow's Nest Pass Coal Co., of British Columbia, is rapidly building up a very large export trade with Montana and the Great Northern Railway and others. The annual production of 1901 and the three previous years was as follows: 1901, 425,350 long tons; 1900, 242,245 long tons; 1899, 116,200 long

THE WORLD'S PRODUCTION OF COAL IN METRIC TONS

tons; 1898, 8,996 long tons. It is said that the larger part of the coal supply of southeastern Alaska, the majority of the California coast cities, and the Southern Pacific Railway is derived from the collieries of Vancouver Island, B. C.

*China.*—A new coal field near Ngankin, on the Yangtse river, Province of Anhui, China, is expected to be in full operation during 1902. The mines are

within a few hours' steamer travel of Shanghai. The coal field is said to be of great extent, and to furnish coal of a very high quality.

*Europe.*—Coal is said to have been discovered recently in the mountains of Bohemia which is equal in quality and in facility of operation to any in Austria. The production of coal in Great Britain during 1901 amounted to 219,046,945 long tons, against 225,181,300 long tons in 1900, a decrease of 6,134,355 long tons during the year, due very largely to depression in the iron and steel and other industries. The coal exported in 1901 amounted to 41,878,345 long tons, against 46,108,011 long tons in 1900, a decrease of 4,229,666 long tons during the year. A royal commission, consisting principally of railway and coal mining experts was appointed early in 1902 to inquire into the extent and available resources of the coal fields of Great Britain. The output of coal in France was 33,404,298 metric tons in 1900, against 32,862,712 metric tons in 1899. The production of coal in Germany and Luxemburg, including brown coal, during 1901, was 152,628,931 metric tons, against 149,788,256 metric tons in 1900, a decrease of 2,840,675 metric tons during the year. The exports of coal, including lignite, during 1901 were 15,287,985 metric tons, against 15,328,600 metric tons in 1900, while the imports of the same products were 14,406,332 metric tons in 1900, against 15,344,362 metric tons in 1900.

*India.*—While coal is pretty generally distributed throughout India and Burma, five-sixths of the supply comes from the coal fields of Bengal, which produced from 154 collieries in 1895, 3,037,920 tons, all the rest of India producing from 18 collieries but 809,093 tons during the same year. Since that time coal mining in Bengal has increased enormously. The Indian Empire produced from 287 coal mines 6,095,438 tons in 1900, 4,954,965 tons of which was produced by Bengal, at an average selling price of 4s. 5d. per ton.

*Japan.*—The island of Kinshu furnishes the bulk of the coal supply of the Empire, or about 3,000,000 tons out of a total production of 4,000,000 tons during 1900. The principal coal district lies in the basin of the river Onga, which enters the sea at the port of Wakamatsu. The coal in the upper part of the basin is of superior quality. The Takashima deposits, near Nagasaki, furnish the best coal of Japan. The mine situated in Hizen County, Kumamoto Protectorate, was the first in the Empire to be developed on European lines. The Hiro-Yama mines, in Higo County, are owned by the Kinshu Coal & Railway Co. The famous Miike deposit in Chikugo County is the property of Mitsu & Co., of Tokio. Next to Takashima, the Miike is the best coal in Japan. Four mines in the coal fields on Hokkaido Island are being operated by the Hokkaido Coal Mines & Railway Co. with an annual production of about 1,500,000 tons. The Onodo mines, in Nagato County, Japan Island, furnished an output of about 200,000 tons in 1900, and coal is also being mined to a considerable extent in Ibariki County in the east part of the island.

*Mexico.*—The coal fields of Las Esperanzas, State of Coahuila, adjoin and run parallel to the Sabinas basin, and are distant about 85 miles southwest of Eagle Pass, Tex. They were discovered in 1899, and development was begun early in 1900 by the Mexican Coal & Coke Co., which owns about 6,000 acres, comprising the only part of the field which is economically workable. The coal is a soft

bituminous coking coal of good quality, and the coal measures are from 6 to 24 ft. in thickness. During 1901 the company built and partially put into operation a block of 224 coke ovens, of which 100 were operated during the latter part of the year, and the balance were started up early in 1902. The *Compañía Fundidora de Fierro y Acero de Monterey* owns 30,000 acres of land in the Laredo coal field, near Monterey. Anthracite coal is found in the States of Sonora, Michoacan, Vera Cruz, Guerrero, Oaxaca, and Puebla.

#### THE ANTHRACITE COAL TRADE IN 1901.

BY SAMUEL SANFORD.

THE year 1901 will always be memorable in the history of the anthracite coal trade. Not only was the production the largest on record, exceeding that of 1900 by 24,983,083 tons, but the prices secured have been thoroughly satisfactory to producers. This combination of large output and higher prices is a decided novelty. It was due to a heavy demand and a successful attempt to put the trade on a firmer basis. At the opening of 1901, Morgan interests were in control of 63% of the total tonnage annually shipped out of the anthracite region, enabling them to maintain by strength of position whatever plans they wished. This "community of interests," so-called, had for its working head the Temple Iron Co., a company organized with very liberal charter provisions in 1899. The directors of this company include presidents of all the coal-carrying roads under Morgan control. The company is thus not a trust in the usual acceptance of that term, and cannot be easily reached by any State or United States statutes governing illegal competition or restriction of output. Its directors can discuss policies quietly, there are no necessities for agreements, and harmony is absolute.

The year opened with anthracite in demand. The market had not recovered from the effect of the miners' strike during September and part of October, though the mines in December had shipped something like 5,000,000 tons of coal. Though the weather was mild, activity in the East was greater than for 30 years, while Western trade was also good. The regular prices quoted for free-burning white ash coal, f. o. b. New York, were broken \$4, egg \$4.25, stove and nut \$4.50, pea \$3.

During the mild weather of January demand held up well, with the steam sizes and stove and chestnut bringing full circular prices and at some points a premium of 25c. per ton for prompt delivery, though broken and egg slightly declined in prices. February was a month of cold weather and high winds, and the consumption of coal increased. Prices were firm at \$3.65 for broken, \$4 for egg, and \$4.50 for stove and chestnut. March likewise was a cold and stormy month and the consumption of fuel for domestic purposes was very heavy. Prices showed no change. All the coal that the mines could send forward was taken, and by the opening of April supplies everywhere were unusually low. At the head of Lake Superior, docks were bare. Consumers in Chicago territory were taking unusually large all-rail shipments. At inland points East the market was firm and every condition was favorable for an unusually good spring trade. The

various mining and transportation companies issued a spring price list on April 1, which differed materially from any issued before. It named certain prices for the prepared sizes and offered discounts for prompt buying. Thus the New York Harbor f. o. b. prices for free-burning white ash coal, f. o. b. were: Broken \$4, egg \$4.25, nut and stove \$4.50. The steam sizes—pea, buckwheat and rice—were not included, but were to be sold at the discretion of the various companies. The discounts offered from the list prices were 50c. per ton for April, 40c. for May, and so on, till full list prices were in force again, September 1. Another novelty was that sales for forward delivery were abolished. Coal shipped in April received April discounts, but no orders at April discounts were to be taken for May delivery. This change was of particular importance to the Western trade. In addition, discounts to middlemen and jobbers were largely abolished, and prices were made the same to all dealers. It was realized, particularly by the Eastern trade, that back of the list was the power to enforce it. So the price list received respectful attention and brought out considerable early buying by the prudent. Fears of a general strike of the miners on May 1 to secure recognition of their union had doubtless lead to considerable buying during March, beyond that due to the weather. The danger of a strike was removed, however, when the Reading and other companies posted notices about March 12 that the 10% advance in wages granted after the strike of 1900 would remain in force a year longer. Trade during April was generally better, particularly at Eastern points, than had usually been the case in previous years. In the West trade was generally quiet. May began with the demand in the East still good and prices ten cents a ton higher, as per schedule, that is \$3.60 for broken, \$3.85 for egg, and \$4.10 for stove and chestnut, f. o. b. New York Harbor shipping port. Navigation on the lakes was late in opening and a strike of the lake engineers delayed the movement of coal from Buffalo. Buying during the month in the East was liberal, some firms not being able to secure all the coal they wanted at May prices. The movement of coal up the lakes toward the end of the month was heavy. In the East receipts at Boston for the month were 55% greater than in 1900. At the end of May the collieries were working one-half to two-thirds of full time. Supplies in the hands of producers were less on May 31 than on May 1; a most remarkable showing. With warmer weather in June, the market continued surprisingly strong at Eastern points. Buyers in the West apparently did not understand the situation as well as those in the East, though the demand at Chicago from wholesalers was quite active, a most remarkable occurrence. The movement of coal up the lakes continued good. The total shipments from the mines to June 30 amounted to 27,362,187 tons, compared with 22,678,400 tons in 1900, showing the first half year to have been the most active in the history of the anthracite trade.

In previous years, a period of stagnation, known as "midsummer dullness" had usually settled on the coal trade about June 1, lasting until September 1, or even later. In 1901, however, there was no midsummer dullness whatever. A strike of mine firemen affected production in the Wyoming and Lackawanna fields during the latter part of July. The market during August was generally quiet but strong. With prices back to full list figures in September, and the

market good, doubters of the stability of the new order of things were utterly routed. Buying for Western account continued active during September. There were some reports of coal selling for less than list prices, but these reports applied to special grades or conditions and did not affect the market as a whole. By the opening of October most of the collieries were running very nearly full time, with demand good at all points and virtually the only restriction on output was a shortage of cars. This shortage soon became marked and for the rest of the year affected production. By the end of November the Reading collieries and those of some other companies were mining on short time. Demand was strong at both Eastern and Western points. A heavy rain storm in the anthracite region in December did much damage and decreased the December shipments over 500,000 tons. It caused a suspension of shipments on the Lehigh Valley, Central Railroad of New Jersey, and Philadelphia & Reading for nearly two weeks. The year closed with the market very strong and little coal in the hands of producers. The average prices for the prepared sizes of free burning white ash coal for the past two years *f. o. b.* New York Harbor shipping ports compare as follows:—

| Months.            | Broken. |        | Egg.   |        | Stove. |        | Chestnut. |        |
|--------------------|---------|--------|--------|--------|--------|--------|-----------|--------|
|                    | 1900.   | 1901.  | 1900.  | 1901.  | 1900.  | 1901.  | 1900.     | 1901.  |

#### THE ATLANTIC SEABOARD BITUMINOUS COAL TRADE IN 1901.

BY SAMUEL SANFORD.

EXCEPT for the coal shipped to Boston and a few other points beyond Cape Cod from the mines in Nova Scotia, and a limited amount of Georgia, Kentucky, and Tennessee coal that reaches Charleston and Savannah, the soft coal consumed along the Atlantic seaboard comes from Pennsylvania, Maryland, Virginia and West Virginia. The coal is shipped to tide water from the mines over four railroads: the Norfolk & Western, which carries the product of the Pocahontas and Flat Top fields in southwest Virginia and southeast West Virginia, to Norfolk; the Chesapeake & Ohio, from the New River fields to Newport News; the Baltimore & Ohio, from the Piedmont and Cumberland districts in West Virginia and Maryland to Baltimore; and the Pennsylvania system, which carries to Philadelphia the coal from the Clearfield and the Huntington and Broadtop fields in Pennsylvania, and the Cumberland region in Maryland. These roads are now practically under one control, stockholders in the Pennsylvania Railroad Co. having a controlling interest in the three other lines. The general policy of the Pennsylvania Railroad during 1901 was what had been foreshadowed. The shipments of certain coals were restricted to certain markets. For instance, through freight rates were named, that virtually shut out Pocahontas coal from New York Harbor points—a market that can be supplied with Clearfield. This arrangement reduces selling agencies and shortens rail hauls. While there were no changes in the policies of railroads, there were some very large consolidations of interests in the mining fields, particularly in West Vir-

ginia, which had for their object the securing of more favorable freight rates and a uniform distribution of cars at the mines. In fact, some may be said to act as sales agencies rather than mining companies. A notable purchase late in the year was that of the Flat Top Land Association by the Norfolk & Western Railroad. This purchase is in line with certain other tendencies shown by those in control of the Pennsylvania Railroad. Great activity is to be expected in West Virginia, as the mines nearer tide water are exhausted.

The year opened with the market in fair shape. Such coals as Pocahontas, New River, and George's Creek, were in demand, while Clearfield and the poorer grades were selling slowly; but buying fell off and by the end of the month there was a plentiful supply of even the better grades. The shipping ports were blocked with coal and the railroads were putting embargoes on many producers to keep cars from accumulating at tide water. The Long Island Sound trade was in easier shape than in two years. Freight rates for coast-wise shipments were unusually low. Clearfield coal was selling at \$2.40 and \$2.65 f. o. b. New York Harbor ports, with better grades at \$2.85 and over. The consumption of coal did not keep pace with the amount offered for sale, and there was all through February and into March, an accumulation of coal at tide water. Some lots of low-grade coal, on which demurrage was accruing, sold as low as \$2.10 f. o. b. New York Harbor shipping ports.

In March all producers cut their outputs sharply. The Bituminous Trade Association held several sessions in New York City, at which it was given out that the prospect for uniform prices was better than ever, and that everything presaged a successful year for the association. There were rumors of trouble in some of the mining regions during March that probably brought out a little speculative buying, but the danger of a general strike in the Pennsylvania fields passed when the operators agreed to pay a mining rate of 60c. per ton for the year. Late in the month producers announced that they would extend old prices for the coming year. These were as follows: Best grades f. o. b. New York Harbor shipping ports, \$2.85; Clearfield, \$2.65; best grades f. o. b. Philadelphia, \$2.50; Clearfield, \$2.35; best grades f. o. b. Baltimore, \$2.43; Clearfield, \$2.28; New River coal, f. o. b. Newport News, \$2.50; Pocahontas f. o. b. Norfolk, \$2.50; all prices net to the companies. April opened with the trade still dull, particularly in the far East and along Long Island Sound. The situation did not change materially during May; the better grades were generally firmly held, but the poorer grades were in abundant supply, particularly at Eastern points, and sold at discounts. Heavy arrivals at Boston led to long delays in unloading and considerable coal was sold under demurrage. June found the trade quiet and dull, with tide-water shipping ports still congested with cars waiting for vessels and abundant supplies at most ports beyond Cape Cod. By the end of June conditions began to improve. Prices, however, did not change much, Clearfield at the beginning of July selling at \$2.35 f. o. b. New York Harbor shipping ports, while the better grades were \$2.85. Trade during July showed very little change. The better grades of coal were firmly held while the poorer grades were in plentiful supply and sold at discounts. By the end of the month labor troubles, which had interfered with industrial activity at many points, were

about over, and as mills resumed, demand improved. By the middle of August a very fair tonnage was going from the mines, particularly for points beyond Cape Cod.

The market continued to improve during September, though the lower grades were still in over supply. By the middle of October trade was in excellent shape. Demand was very heavy, particularly at Long Island Sound points and in all-rail territory, while New York Harbor trade was steadily improving. Car supply at the mines, which, up to the first of October, had been on the whole sufficient, by the middle of the month was less than 50% of the demand, and varied from 25 to 50% for the balance of the year. During November and December the demand for coal at Long Island Sound and New York Harbor points became very pressing, and all grades sold at full circular figures. By the end of the year consumers were regularly paying \$4 a ton for spot coal f. o. b. at Long Island Sound ports, and \$3.50 a ton at New York Harbor shipping ports, while the coal thus obtained was very often of very inferior quality. In some cases firms in the bunker trade at New York Harbor paid as high as \$4 for spot coal.

THE MANUFACTURE OF COKE IN THE UNITED STATES WITH SPECIAL REFERENCE  
TO THE MARKETS FOR BY-PRODUCTS.

BY F. SCHNIEWIND.<sup>1</sup>

THE manufacture of coke in by-product ovens has now been firmly established in the United States. The long existing aversion against the use of "by-product coke" in blast furnaces and foundries has been dispelled. As a matter of fact, it has been demonstrated on a most extensive scale that the opinion a few years ago prevalent throughout the United States, *viz.*, that the Connellsville beehive coke is a *conditio sine qua non* for modern and economic blast furnace practice, is absolutely without foundation. With the by-product ovens a coke equal and sometimes even superior to the Connellsville beehive coke has been produced from coals which were considered inferior, because they would not coke well in beehive ovens. Furthermore, it has been demonstrated on a large scale that illuminating gas can be obtained as a by-product from coke ovens.

These two achievements forebode the erection of a considerable number of by-product coke ovens, and it is therefore of interest to inquire into the prospects for disposing of the by-products in the American markets.

Before entering upon the description of the coke ovens and statistics of the by-products recovered in the United States some general statistics are given which demonstrate plainly the marvelous development of the industries of the United States. These figures are of considerable interest in connection with the subject, as they bear directly upon the ultimate maximum production of by-products which may occur if the present wasteful methods in the utilization of fuel, coupled with the complete destruction of these by-products, are abandoned. Reference will be made frequently to the corresponding statistical data of European countries in order to obtain from them an idea of the possible extent of the consumption of these products in the United States.

<sup>1</sup> I wish to acknowledge my indebtedness to Mr. C. G. Atwater for his valuable assistance in the revision of this paper.

**Coal Statistics.**—No other statistics will show the development of the industries in any country so accurately as the consumption of coal, which is the foundation of most industries. By rapid strides the United States has taken the lead among all manufacturing countries, and with the tremendous possibilities presenting themselves in this country, the contingency that any other country may dethrone the United States from its first rank is almost to a certainty excluded. The world's production of coal, including anthracite, bituminous, and lignite, is given on page 128 of this volume, and the graphical chart on page 129 illustrates in a more striking manner the rapid growth of the United States, as compared with the other principal countries. In order to obtain, however, an exact view of the development of the various countries, the imports and exports also should be taken into consideration, and by allowing for these factors the domestic consumption of various countries is as given in the subjoined table, which has been compiled from *THE MINERAL INDUSTRY*, Vol. IX.

PRODUCTION, EXPORTS, IMPORTS, AND CONSUMPTION OF COAL (INCLUDING COKE)  
IN THE PRINCIPAL COUNTRIES OF THE WORLD. (SHORT TONS.)

| Countries.                | Production. | Imports.   | Exports.   | Consumption. | Consumption per Capita. |
|---------------------------|-------------|------------|------------|--------------|-------------------------|
| United States, 1900.....  | 268,242,408 | 2,298,945  | 7,646,225  | 262,985,128  | 3.46                    |
| United Kingdom, 1900..... | 252,107,730 | 11,143     | 53,011,224 | 199,107,649  | 4.759                   |
| Germany, 1900.....        | 120,424,054 | 17,676,952 | 20,891,491 | 117,709,515  | 2.087                   |
| France, 1900.....         | 36,477,111  | 16,062,179 | 1,381,851  | 51,237,058   | 1.825                   |
| Belgium, 1900.....        | 25,733,904  | 4,101,608  | 8,067,218  | 21,748,288   | 3.259                   |

NOTE.—Allowance is made in the above table for imports and exports of coke. 7 lb. coke is considered as representing 10 lb. coal.

The figures given in the above table do not afford an exact comparison of the various countries, because the United States has other large sources of fuel besides coal, viz., petroleum and natural gas, of which practically none are found in the other prominent industrial countries. The detailed production of coal, petroleum and natural gas in the United States during 1901 will be found under their respective captions elsewhere in this volume. By estimating the coal equivalent for the petroleum produced at 3.22 bbl. (of 42 gal.) per short ton of coal and including an approximate coal equivalent of the natural gas production, the total fuel production (exclusive of wood) should be increased by 19,650,107 short tons of coal for the former and 7,018,000 short tons for the latter, making in all 294,910,515 short tons of total fuel produced in terms of coal.

A revision of the fuel production of the United States in 1900 to include this additional fuel consumption allowing for the exports of petroleum and the imports of natural gas is as follows:—

COAL EQUIVALENT OF MINERAL FUEL CONSUMPTION OF THE UNITED STATES  
IN 1900. (SHORT TONS.)

| Production. | Imports.  | Exports.   | Consumption. | Consumption per Capita. |
|-------------|-----------|------------|--------------|-------------------------|
| 294,910,515 | 2,298,980 | 14,803,565 | 282,443,830  | 3.7                     |

From the foregoing table the quantity of wood used as fuel is omitted because no statistics of its use are available. There should also be taken into consideration the use of electricity generated by water power for light, heat, and power, which is especially important in connection with a large number of electro-metallurgical processes. Under certain conditions electricity is able to displace coal and other mineral fuels, but no statistics concerning its consumption in this special field are available. Among all mineral fuels coal is the chief source of energy, and while the United States occupies the first position in regard to quantity of output, it still must concede to the United Kingdom the first position in regard to consumption per capita.

*Uses of Bituminous Coal.*—No statistics are available to show the purposes for which bituminous coal is used in the United States, but for the United Kingdom Mr. George Beilby<sup>2</sup> has published a table showing the consumption of coal during 1898 by the various industries in that country from which the following table has been compiled:—

CONSUMPTION OF COAL IN THE UNITED KINGDOM DURING 1898.

|                                                        | Long Tons.         | %            |
|--------------------------------------------------------|--------------------|--------------|
| <i>Coal for the generation of power in industries:</i> |                    |              |
| Railways.....                                          | 11,000,000         | 6.9          |
| Coasting steamers.....                                 | 7,000,000          | 4.4          |
| Mines.....                                             | 10,500,000         | 6.6          |
| Factories.....                                         | 39,000,000         | 24.7         |
| Miscellaneous.....                                     | 8,500,000          | 5.3          |
|                                                        | 76,000,000         | 47.9         |
| <i>Coal for the generation of heat in industries:</i>  |                    |              |
| Blast furnaces.....                                    | 17,000,000         | 10.8         |
| Steel and malleable-iron works.....                    | 11,000,000         | 6.9          |
| Other metallurgical works.....                         | 1,500,000          | 0.9          |
| Chemical works, potteries and glass works.....         | 5,000,000          | 3.1          |
| Gas works.....                                         | 18,000,000         | 8.2          |
|                                                        | 47,500,000         | 29.9         |
| <i>Coal for domestic purposes.....</i>                 | <i>35,000,000</i>  | <i>22.2</i>  |
| <b>Total.....</b>                                      | <b>158,500,000</b> | <b>100.0</b> |

Of the total amount of bituminous coal (158,500,000 long tons) only a very small percentage is subjected to dry distillation with recovery of by-products, as given in the subjoined table:—

COAL SUBJECTED TO DRY DISTILLATION IN THE UNITED KINGDOM IN 1898.

|                                              | Long Tons.        |
|----------------------------------------------|-------------------|
| Gas works.....                               | 18,000,000        |
| By-product coke ovens.....                   | 1,250,000         |
| Blast furnaces with by-product recovery..... | 2,000,000         |
| <b>Total.....</b>                            | <b>16,250,000</b> |

This table does not include the coal coked in beehive ovens without the recovery of by-products, which amounts to approximately 12,500,000 long tons. The portion of coal carbonized with loss of by-products is therefore 42.5% of the total coal carbonized, the total being 28,750,000 long tons.

<sup>2</sup> *Journal of the Society of Chemical Industry*, 1899, Vol. XVIII., p. 648.

The conditions in the United States are somewhat different from those in the United Kingdom, as indicated in the following table:—

COAL SUBJECTED TO DRY DISTILLATION IN THE UNITED STATES DURING 1900.

|                                                                | Short Tons.   |
|----------------------------------------------------------------|---------------|
| Gas works.....                                                 | 2,100,000     |
| By-product ovens.....                                          | 1,547,665     |
| Total short tons.....                                          | 3,647,665     |
| Coal coked in beehive ovens (without recovery of by-products). | 30,576,790    |
| Coal carbonized with loss of by-products.....                  | 90% of total. |

The amount of coal carbonized in gas works is computed later in this section. The amount of coal coked in by-product ovens is derived from a table showing the manufacture of by-product coke in 1900.<sup>3</sup> The yield of coke in by-product ovens has been assumed at 75%, which may be considered a fair average. The total quantity of coal coked in 1900 was 32,113,543 short tons, and by deducting the 1,547,665 tons mentioned above the amount of coal carbonized in beehive ovens was 30,565,878 tons.

The situation in other countries may differ to some extent, but it is certain that an amazing waste takes place in all countries by destroying the valuable by-products which could be recovered by subjecting the coal to dry distillation before using it. The process of dry distillation of the coal with the production of a smokeless coke and large quantities of illuminating gas and fuel gas suggests itself most forcibly as a solution of the much discussed smoke problem. This subject has been fully treated elsewhere.<sup>4</sup>

*Coke and By-Product Ovens.*—The development of the coke industry in the United States has kept pace with the general industrial development. The following table<sup>5</sup> shows the number of coke ovens and the production of coke by States:—

COKE PRODUCTION OF THE UNITED STATES FOR THE YEAR 1900.

| State or Territory.    | Ovens  |           | Coke Produced. | State or Territory. | Ovens      |           | Coke Produced. |
|------------------------|--------|-----------|----------------|---------------------|------------|-----------|----------------|
|                        | Built. | Building. |                |                     | Built.     | Building. |                |
| Alabama.....           | 6,529  | 690       | Net Tons.      | New Mexico.....     | 126        |           | Net Tons.      |
| Colorado (a).....      | 1,438  |           | 2,110,837      | New York (b).....   | 80         | 554       | 44,774         |
| Georgia.....           | 480    |           | 618,755        | Ohio.....           | 369        | 60        | 72,116         |
| Illinois.....          | 154    |           | 73,928         | Pennsylvania.....   | 32,548     | 2,310     | 13,789,698     |
| Indiana.....           | 54     |           | 2,631          | Tennessee.....      | 2,107      | 340       | 476,422        |
| Indian Territory.....  | 230    |           | 38,141         | Utah (a).....       | 304        |           |                |
| Kansas.....            | 91     |           | 5,948          | Virginia.....       | 2,331      | 300       | 695,186        |
| Kentucky.....          | 458    | 3         | 95,532         | Washington.....     | 90         |           | 22,327         |
| Massachusetts (b)..... | 400    |           |                | West Virginia.....  | 10,249     | 1,306     | 2,365,420      |
| Michigan.....          |        | 30        |                | Wisconsin.....      | 120        |           | 49,006         |
| Missouri.....          | 10     |           | 2,087          | Wyoming.....        | 74         |           | 14,501         |
| Montana.....           | 342    | 111       | 54,731         | Total.....          | (c) 58,484 | (d) 5,804 | 30,532,348     |
| New Jersey.....        |        | 100       |                |                     |            |           |                |

(a) Colorado includes production of Utah. (b) Production included in Pennsylvania. (c) Includes 945 Semet-Solvay, 690 Otto-Hoffmann, and 60 Newton Chambers by-product ovens. (d) Includes 150 Semet-Solvay and 945 Otto-Hoffmann by-product ovens.

<sup>3</sup> *Mineral Resources of the United States*, 1900.

<sup>4</sup> "The Production of Illuminating Gas from Coke Ovens," by Dr. F. Schniewind, paper read before the Gas Section of the Engineering Congress at Glasgow. Reprinted in *Progressive Age*, Oct. 15, 1901; and in part in *Iron Age*, Nov. 28, 1901.

<sup>5</sup> *Mineral Resources of the United States*, 1900.

The following ovens were in operation or in course of building in the United States during 1900:—

NUMBER OF COKE OVENS IN OPERATION AND IN COURSE OF BUILDING IN THE UNITED STATES DURING 1900.

|                             |               |
|-----------------------------|---------------|
| (a) By-product ovens :      |               |
| Otto-Hoffmann system.....   | 1,626 ovens.  |
| Sarnet-Solvay system.....   | 436 ovens.    |

|                             | <hr/>         |
| (b) Beehive ovens.....      | 2,181 ovens.  |
|                             | 62,107 ovens. |
| Total .....                 | <hr/>         |
|                             | 64,288 ovens. |

The rapid progress of the coke production in the United States during the past five years is evident from the following table, compiled from *The Engineering and Mining Journal*, January 18, 1902, and *The Mineral Resources*, 1900:—

PRODUCTION OF COKE IN THE UNITED STATES AND THE CONNELLSVILLE DISTRICT, 1897-1901.

| Year.     | United States.<br>Short Tons. | Connellsville District. |                                                 |
|-----------|-------------------------------|-------------------------|-------------------------------------------------|
|           |                               | Short Tons.             | Per Cent. of Total Production of United States. |
| 1897..... | 12,223,984                    | 6,860,826               | 51.6                                            |
| 1898..... | 16,047,209                    | 8,315,350               | 51.1                                            |
| 1899..... | 19,663,569                    | 10,390,335              | 52.8                                            |
| 1900..... | 20,533,846                    | 10,020,907              | 48.9                                            |
| 1901..... | 21,790,868                    | 10,235,943              | 45.9                                            |

The Connellsville district is gradually losing its dominant position as a producer of blast furnace coke. In 1880 it produced 66.1% of the coke supply of the United States; in 1900 only 48.9%. The Connellsville coal basin is being exhausted and other coal fields are being developed which have produced a high grade blast furnace coke in by-product coke ovens.

*Quality of Coke.*—The coke produced in by-product ovens has proved admirably adapted for furnace use. At the Canal Dover Furnaces, in August, 1900, a test under the direction of Mr. A. E. Uehling of coke made in Otto-Hoffmann by-product coke ovens showed that a ton of iron was smelted with 1,787 lb. of by-product coke, while it required 1,885 lb. of standard Connellsville coke to do the same work, a difference of 98 lb. coke per ton of iron in favor of the by-product coke, or a saving of 5.2% on the coke consumption. At the same time the daily production of the furnace was increased 3.3%. At the Cambria Steel Co.'s furnaces at Johnstown, Pa., a two weeks' series of trials of coke made in Otto-Hoffmann by-product coke ovens from local coals and standard Connellsville coke alternated repeatedly and on different furnaces failed to show any difference in the behavior of the furnaces or consumption of fuel.

The coke has shown equally good results in foundry practice. The product of the Everett ovens has been introduced in railroad and domestic service in competition with anthracite and bituminous coal in the vicinity of Boston, and has met with undoubted success. It is probable that the growing objection to

the presence of soft coal smoke in our cities and the economic impossibility of using hard coal outside of a limited territory will cause a much more general adoption of coke as fuel for domestic purposes, for stationary and locomotive boilers, and in kindred fields.

*Pig Iron Statistics.*—The production of pig iron in the United States during 1901 was 15,878,354 long tons, which is classified as to the fuel used in its production in the table on page 380 of this volume. The bulk of the pig iron is manufactured with coke as fuel, and approximately one short ton of coke is required for the production of one long ton of pig iron. In connection with the production of coal and coke it is interesting to note the production of pig iron in the principal countries of the world which is best shown by the diagrammatic chart on page 388, elsewhere in this volume.

Another interesting fact in connection with the development of the pig iron industry of the world is the per capita consumption of the principal countries, which has been compiled by Dr. H. Rentzsch\* as follows:—

PER CAPITA CONSUMPTION OF PIG IRON IN THE PRINCIPAL COUNTRIES  
OF THE WORLD.

|                            | Pounds. |                     | Pounds. |
|----------------------------|---------|---------------------|---------|
| Austria-Hungary.....       | 72.7    | Russia.....         | 57.3    |
| Belgium.....               | 414.4   | Sweden.....         | 215.2   |
| Canada.....                | 92.6    | Switzerland.....    | 108.6   |
| France.....                | 154.3   | United Kingdom..... | 418.6   |
| Germany and Luxemburg..... | 369.3   | United States.....  | 379.1   |

The above table clearly shows that up to the present time the United States has only reached a per capita consumption of pig iron which places it on a level with the other large manufacturing nations, but it may reasonably be expected that in the future the iron industry of the United States will not only increase in proportion to the increase of population, but even at a greater rate on account of the increasing use of steel in certain branches not so extensively developed in other countries, especially the use of structural steel for office buildings, steel cars, etc.

*Illuminating Gas.*—According to the *Census Bulletin*, No. 123, the total sales of gas during 1900 (exclusive of coke-oven gas and leakage) was 67,094,000,000 cu. ft. The magnitude of the by-product coke oven industry already established in the United States is evident from the fact that the ovens in operation and in course of erection generate and treat for by-products fully 50,000,000,000 cu. ft. of gas per annum. The annual surplus (not used by the ovens) may be estimated at 15,000,000,000 cu. ft., or about 25% of the annual gas consumption of the country. The following table has been compiled from Brown's *Directory of American Gas Companies*:—

PRODUCTION OF ILLUMINATING GAS IN THE UNITED STATES DURING 1900.

|                               | Cu. Ft.               |
|-------------------------------|-----------------------|
| Coal gas works.....           | 8,270,000,000         |
| Water gas works.....          | 17,250,000,000        |
| Coal and water gas works..... | 42,628,000,000        |
| Miscellaneous.....            | 740,000,000           |
| <b>Total.....</b>             | <b>68,888,000,000</b> |

\* *Stahl und Eisen*, Dec. 1, 1901, and March 15, 1902.

From this table it is apparent that the gas production in the United States, per capita, taking the population according to the Census of 1900 at 76,303,387, is 903 cu. ft., a quantity which is considerably lower than that of the United Kingdom (see page 142). This may be explained to some extent by the very extended use of electric lighting in the United States, and the extensive use of natural gas in certain manufacturing districts, but even with these allowances, the United Kingdom is far ahead of the United States in the per capita consumption of gas.

In recent years the production of coal gas as compared with water gas has considerably increased, chiefly for two reasons, *viz.*: (1) The greatly increased price of oil. (2) It has been recognized that an admixture of coal gas to carburetted water gas is coupled with a considerable reduction in the amount of oil used per candle power, calculated on the blue water gas. As far as may be estimated from the data available the relative proportion of coal and water gas in gas works producing both is 20% coal gas and 80% water gas, therefore the estimated production of coal gas and water gas in the United States during 1900 is as follows:—

## COAL GAS AND WATER GAS SOLD IN THE UNITED STATES DURING 1900.

|                                                               | Coal Gas.<br>Cu. Ft. | Water Gas.<br>Cu. Ft. |
|---------------------------------------------------------------|----------------------|-----------------------|
| Works producing pure coal gas.....                            | 8,270,000,000        |                       |
| Works producing pure water gas.....                           |                      | 17,250,000,000        |
| Works producing mixed coal gas (80%) and water gas (80%)..... | 8,596,000,000        | 34,102,000,000        |
| Total .....                                                   | 16,796,000,000       | 51,352,000,000        |

It is worthy of note that up to the present time there has been installed by the United Gas Improvement Co., of Philadelphia, sufficient apparatus to produce annually 110,032,900,000 cu. ft. of carburetted water gas.

The amount of gas sold in 1901 and the amount of coal carbonized may be estimated as follows:—

|                                   | Cu. Ft.        |
|-----------------------------------|----------------|
| Coal gas production, 1900 .....   | 16,796,000,000 |
| Estimated increase for 1901 ..... | 1,680,000,000  |
| Sales, 1901 .....                 | 18,476,000,000 |
| Leakage, estimated at 8% .....    | 1,478,000,000  |
| Coal gas production, 1901 .....   | 19,954,000,000 |

As stated above, the coal gas production during the last two or three years has increased rather more than the water gas production, hence the average increase in the coal gas production has been placed at 10%, while the United States Census for 1890 and 1900 shows an increase in the entire gas production of 86.9% for the decade.

The amount of coal consumed (exclusive of boiler fuel) by gas works in 1900 is given in the United States Census as follows:—

|                                                            | Short Tons. |
|------------------------------------------------------------|-------------|
| Coal consumed by gas works (exclusive of boiler fuel)..... | 2,487,587   |
| Coke consumed, 15,314,798 bushels = .....                  | 304,300     |
| Coal carbonized.....                                       | 2,791,587   |
| Coal and coke gasified in water-gas plants.....            | 2,100,000   |
|                                                            | 691,587     |

consumption of 28 lb. coal or coke per 1,000 cu. ft. carbonized. The production of water gas in the United States for 1900 was 13,610,000 cu. ft. The consumption of oil is given in the United States Census of 1900 as 1,300,000 gal., and assuming an average consumption of 3.75 gal. of oil per cu. ft. of water gas, the production of the latter is 344,000,000 cu. ft. This production is estimated on the basis of Brown's estimate of 13,610,000 cu. ft. From the closeness of these estimates they are substantially correct.

**Producing Illuminating Gas in the United Kingdom.**—The Government returns for the production of illuminating gas in the United Kingdom are given in the *Journal of Gas Lighting*, February 6, 1900, and January 21, 1901, as follows:—

PRODUCTION OF ILLUMINATING GAS IN THE UNITED KINGDOM, 1898-1900.

| Year | Coal Carbonized.  | Coal Gas.       | Water Gas.     | Acetylene Gas. | Total Gas.      |
|------|-------------------|-----------------|----------------|----------------|-----------------|
|      | Tons of 2,240 Lb. | Cu. Ft.         | Cu. Ft.        | Cu. Ft.        | Cu. Ft.         |
| 1898 | 12,841,817        | 180,742,718.682 | 7,404,193,550  | 82,550         | 188,146,994,782 |
| 1899 | 13,610,000        | 187,078,455.972 | 10,077,020,210 | 75,390         | 147,155,557,481 |
| 1900 | 13,900,328        | 139,899,277.976 | 12,108,452,109 | 81,408         | 152,007,811,467 |

The population of the United Kingdom in 1891 was 37,888,000 inhabitants. The consumption of illuminating gas in 1891 was 108,694,259,471 cu. ft. The consumption of illuminating gas per capita in 1891 was 2,869 cu. ft. The population of the United Kingdom for the year 1900 has been given at about 41,154,000, consequently the gas consumption per capita was 3,667 cu. ft., which is a very high average. In the United States the per capita consumption of illuminating gas for the year 1900 was given above, viz., only 903 cu. ft., which, however, excludes the consumption of natural gas.

#### THE DEVELOPMENT OF BY-PRODUCT COKE OVENS.

Formerly beehive ovens only were operated for the manufacture of coke, and they still predominate in the United States and in the United Kingdom.

Mon. E. Coppée designed the first successful "retort oven," which found its largest use in Germany, where the firm of Dr. C. Otto & Co. built nearly 8,000 ovens of the "Otto-Coppée" type. These ovens produce a higher percentage of coke than the wasteful beehive oven, and they also reduce the cost of labor.

The next step in the development was the recovery of tar and ammonia. A large number of ovens were designed, but of these the firm of Dr. C. Otto & Co. introduced the most successful types (especially the Otto-Hoffmann regenerative type) and erected in all 4,245 ovens, chiefly in Germany, for the saving of by-products. These ovens are built in the United States by the United Coke & Gas Co., which has still further improved the design especially for the manufacture of illuminating gas.

The number of by-product coke ovens in the United States and Canada is as follows:—

## BY-PRODUCT COKE OVENS IN THE UNITED STATES IN 1901.

| Company.                                           | Location.                | No. of Ovens. | Use of Coke.                    | Use of Gas.      |
|----------------------------------------------------|--------------------------|---------------|---------------------------------|------------------|
| <b>Otto-Hoffmann ovens:</b>                        |                          |               |                                 |                  |

(a) In course of construction.

## A MODERN OTTO-HOFFMANN COKE OVEN PLANT.

In order to adapt the Otto-Hoffmann process, as practiced in Germany, to the new requirements as presented in the United States, and especially for the manufacture of illuminating gas, many changes were necessary. The following description is of a modern Otto-Hoffmann plant composed of 100 by-product coke ovens, as erected by the United Coke & Gas Co., of New York.<sup>1</sup>

Bituminous coal, when exposed in closed retorts to a high temperature, gives the following products: (1) Coke, remaining as a residue in the retort; (2) tar; (3) gas liquor, from which subsequently by distillation ammonia products are obtained, and (4) coal gas, which contains benzol and its homologues in vapor form. From the gas there are at times additional products extracted—cyanogen and sulphur—but this will not be discussed here.

In order to show the variations in the yields of different coals, the following results obtained on some coals in Otto-Hoffmann coke ovens are given:—

## YIELDS OF VARIOUS COALS USED IN OTTO-HOFFMANN OVENS.

| Plant Used.                                     | Coke. | Tar. | Ammonium Sulphate. | Total Gas per 2,000 Lb. |
|-------------------------------------------------|-------|------|--------------------|-------------------------|
| <b>Average operating results:</b>               |       |      |                    |                         |
| Dominion (Cape Bryton) coal, Everett, Mass..... | 72.83 | 4.99 | 1.010              | 9,000                   |
| Youghiogheny (Pa.) coal, Glassport, Pa.....     | 75.60 | 5.07 | 1.100              | 9,000                   |
| Westphalian coal (Germany).....                 | 74.50 | 3.70 | 1.280              | 9,600                   |
| <b>Distillation test:</b>                       |       |      |                    |                         |

**Ovens.**—The ovens are arranged in two groups or batteries of 50 ovens each, as illustrated in Figs. 1, 2 and 3. Each oven (1) is an air-tight retort, consisting of a rectangular chamber 43 ft. 6 in. long × 17 in. wide × 6 ft. 6 in. high. The

<sup>1</sup> United States Patents Nos. 687,595, June 27, 1899; 673,928, May 14, 1901; 684,540, Oct. 15, 1901; 698,062, 698,063, Apr. 23, 1902. Further patents pending.

each retort is 4 short tons of coal per charge; coking time, 24 hours. The retorts, with average coking coal yielding 75% coke, is therefore 3 tons of coke. The retorts are placed side by side, and are supported on a steel lattice-work of light I-beams, running the length of the battery, which is supported by steel columns. This allows the brickwork to be inspected at all points. The key feature, however, is the uniform distribution of fuel gas to the combustion chambers heating the oven retorts. The retorts are separated by hollow brick walls, divided into 10 compartments (2), each compartment containing a vertical, flues (3). An air chamber is located directly under the retorts, outside this chamber, and directly under the vertical flues above are 10 combustion chambers (5). The gas supply to each of the

FIG. 1.—CROSS SECTION OF AN OTTO-HOFFMANN BY-PRODUCT COKING PLANT FOR THE MANUFACTURE OF ILLUMINATING GAS.

chambers is controlled independently, and a uniform heat is maintained throughout the entire length of the oven. The air for combustion is admitted through opening (6) in the wall between the air and the combustion chambers. The air is heated to 1,800°F. by a pair of regenerators (7), placed together under the center of the battery and running its entire length. A vertical flue (8) conducts the air from the regenerator to the air-chamber (4), under the oven.

The well-known Siemens principle is used in operating the air regenerators, with reversals every 30 minutes. The fuel gas is reversed at the same time as the air by means of a suitable valve; but the gas is not regenerated. The gas unites with the hot air in five combustion chambers (5), ascends through the vertical flues (3) to a horizontal flue (9) above, through which it passes and descends

through the five chambers in the other end of the oven, thence through the air chamber (4) and vertical flue connection (8) to the regenerator (7) and through the reversing valves to the stack. The regenerators are built entirely independent of the oven structure, so that their expansion does not affect the oven brickwork. Instead of arranging the regenerators directly underneath the ovens, they have been arranged also vertically at the end of the batteries like hot blast stoves.

*Coal Handling.*—A steel coal storage bin (12) of a capacity equivalent to about two days' coal consumption, is placed between the batteries. The coal is elevated to the bin from a hopper (13), placed under the coal-receiving track (14) by a belt or other type of conveyor (15). A coal larry (16) of 8 tons capacity, runs on a track (17) on the top of the batteries and under the coal bin. The larry consists of a long narrow bin with eight spouts in the bottom, through which

FIG. 2.—DETAILS OF CONSTRUCTION OF A MODERN OTTO-HOFFMANN BY-PRODUCT COKE OVEN.

the coal is run into the oven retort through holes in the top of it, and is leveled by means of a bar worked through a small opening in the doors at the ends of the oven. The larry is operated by an electric motor and receives its load of coal from the storage bin, under which it passes.

*Coal Compression.*—A uniformly dense metallurgical coke can be produced, and the output of an oven largely increased by compressing the coal into a mold slightly smaller than the retort and charging the block through the oven door. In order to make a sufficiently solid block it is necessary that the coal should have a certain percentage of water (8 to 12%). Unless the coal carries such an amount it will have to be added. The subsequent evaporation of this water in the coke ovens requires additional gas for heating the ovens; the additional amount

of water vapor has to be condensed (requiring larger condensing capacity) and an increased amount of gas liquor has to be distilled (requiring larger ammonia still capacity). These items form eventually an expense against the saving resulting from the increased capacity of the plant. Generally speaking the answer to the question whether the greater density of the coke is desirable should decide for or against adoption of the coal-compression method. Besides these there are other important points to be taken into consideration which cannot be discussed here.

*Coke Handling.*—Upon the completion of the coking process the oven doors are raised and the mass of 6 tons of coke is pushed upon a movable platform

FIG. 3.—DETAILS OF CONSTRUCTION OF A MODERN OTTO-HOFFMAN BY-PRODUCT COKE OVEN.

(20) by means of a ram (21). The pushing ram, as well as the machine (22) on which it is mounted, are operated by electric motors. The coke, after being pushed upon the platform, is quenched and allowed to cool. The platform (20) is then tilted by an electric motor and the coke slides off into cars (23), which run on a track at the back of the machine.

*Gas Mains.*—The gas distilled from the coal during the coking process is conducted to the condensing house by two independent systems of mains (25 and 26). These mains run on top of the battery for its entire length—one on each side. Each oven is connected to each main by a vertical pipe (27) and valve (28).

During the first part of the process the rich gas is taken off through the rich-gas main (25). The valve to this main is then closed and the balance of the gas is taken off through the poor-gas main (26). When the coking is completed the valve to the poor-gas main is closed, disconnecting the oven from both mains.

*Condensing Plant.*—The difference in the composition of the two fractions of gas is evident from the following table based upon the Dominion Coal Co.'s Cape Breton coal:—

COMPARISON OF RICH AND POOR GAS FROM DOMINION COAL, OBTAINED IN PRESENT OPERATIONS AT EVERETT.

|                                             | Rich Gas<br>(surplus). | Poor Gas (Oven-<br>heating Gas). |

The cooling of the gas and the removal of tar and ammonia are done in the usual apparatus, hence it is not necessary to discuss it here in detail. Both the rich and poor gases are treated in the same manner. The following is the sequence of the apparatus as shown in the general sketch of a gas plant for coke ovens, Fig. 4: (1) and (7) are air coolers; (2) and (8) are multitubular water coolers; (3) and (9) are tar extractors; (4) and (10) are exhausters; (5) and (11) are second coolers intended to remove the heat produced by the compression of the gas in the exhausters, and (6) and (12) are ammonia washers.

The rich gas when freed of tar and ammonia, leaves the condensing plant and passes through pipe (42) into the purifying plant (37) and from there into a large storage gas holder for illuminating gas, from which it goes into the city. The poor gas, after being treated in the same manner as the rich gas, leaves the ammonia washers (6) and passes through two benzol scrubbers (13) and (14). After having been freed of its benzol, it flows through pipe (15) into the oven gas holder (16). Here it is mixed with producer gas, when necessary, and carried to the ovens for heating by the pipe (17). The benzol extracted from the poor gas is then transferred to the rich gas, so as to increase its candle-power.

The tar-oil by which the gas is washed runs first from tank (18) through the second benzol scrubber (14) into tank (19). From here it is supplied by pump (19-A) into the first benzol scrubber (13). The tar-oil enters from tank (18) with about 0.5% of benzol, leaves washer (13) with about 1.5% of benzol, and is finally collected in tank (20). From here it is fed by pump (20-A) into still (21) in which the benzol is reduced again to about 0.5%. The exhausted oil collects in tank (22). From here it is taken by pump (22-A) through the oil cooler (23) in order to be again supplied to tank (18) for a new absorption.

A small additional plant is needed (which, however, has been omitted in this sketch), by which a small percentage of the oil is revived, in order to keep it active for benzol absorption. This consists of a simple tar still and condenser, in which the tar-oil is freed from most of the naphthaline and other hydrocarbons incidentally absorbed. The presence of an excessive percentage of them in the tar-oil would interfere with a complete benzol absorption.

The benzol vapors which are driven off in still (21) are carried into the rich-gas system by means of a gas current coming from the pressure side of the rich-gas condensing plant. This greatly facilitates the distillation of the tar-oil passing through the still. The mixture of the gas and benzol vapors then passes through pipe (24) preferably to the inlet of the exhausters (10) of the rich-gas condensing plant. In this manner, the vapors do not come in contact with a large body of tar, which would be liable to absorb a part of the benzol.

It is unnecessary to describe here the details of the benzol distilling plant.

FIG. 4.—ARRANGEMENT OF GAS PLANT FOR BY-PRODUCT COKE OVENS OF THE MODERN OTTO-HOFFMANN TYPE.

A great number of these are in operation in connection with German by-product coke plants. The United Coke & Gas Co., however, controls for the United States the Hirzel process of benzol recovery which has been preferred by the German coke plants.

#### AUXILIARY GAS PLANT.

When operating the plant continuously, practically the same amount of surplus gas is obtained every day, and the plant would not be adapted to follow the fluctuations in the gas consumption. The plant is consequently so designed that its surplus gas will meet the minimum requirements in summer time, and the increased requirements in winter are made up by an auxiliary gas plant. Two ways suggest themselves in connection with the by-product coke ovens:—

1. *An Auxiliary Producer Plant.*—Producers are operated preferably on coke screenings and refuse coke, which finds a sale only at a reduced price. The pro-

ducer gas thus obtained is mixed with the poor coke-oven gas and burnt under the ovens. In this manner, more rich gas becomes available. Such a plant is now in operation at the New England Gas & Coke Co.'s works, with exceedingly good results in regard to heat efficiency, *i.e.*, 90% of the fuel value of the coke charged into producers is accounted for in the increased volume of rich gas. (This plan has not been shown in the accompanying sketches.)

2. *Auxiliary Water-Gas Plant.*—Instead of a producer plant, a water-gas plant may be added to the coke ovens, as is indicated in Fig. 4. This plant may be operated in three ways:—

(a) As a producer plant. By shutting valve (27) permanently and opening valve (25) the generator (26) is permanently used as a producer. A mixture of air and steam is blown through the incandescent fuel bed, and the gas, after being scrubbed in (40) passes through pipe (41) into the oven gas holder, where it mixes with the poor coke-oven gas and is sent to the coke ovens for heating.

(b) As a carburetted water-gas plant. By shutting valve (25) and opening valve (27) the plant becomes an ordinary carburetted water-gas plant with generator (26), carburettor (28), superheater (29), washer (30), condensers (31) and (32), and relief holder (34). The carburetted water gas is sent through the exhaustor (35), and through the purifying plant (37) into the large storage holder for illuminating gas. It is evident that such an equipment affords a most valuable reserve in case of coal shortage, strikes, etc.

(c) Combined producer and water-gas plant. When blowing air through the generator, valve (25) is opened and the producer gas passes through scrubber (40) into the oven-fuel gas holder (16). When the fuel bed thus becomes hot, valve (25) is closed and valve (27) is opened, while steam is blown through the generators. The resulting blue water gas passes through the entire set of water-gas apparatus (28 to 32), while, however, no oil is fed into the carburettor. The blue water gas is finally taken from the storage holder (34) by means of exhaustor (35), and mixed with the rich gas coming through pipe (42) at the entrance of the purifying house (37). The mixture of the gas then passes into the storage holder and thence into the city. The candle-power in the rich gas would, of course, be reduced by the admixture of blue water gas, but this is made up by the benzol which is transferred from the poor gas to the rich gas, as described above.

*Quality of Gas.*—The amount of surplus gas thus recovered is given on page 152. The candle-power and caloric value of the gas are higher than those of the average coal gas. The Everett coke-oven gas has 18 to 19 C.P. without further enriching.

#### RECOVERY OF TAR AND AMMONIA.

Tar and gas liquor are obtained in the condensing and scrubbing process through which the gas passes, being collected in large cisterns in which they separate, the heavier tar sinking to the bottom. The tar is drawn off and allowed to stand in order to eliminate the water fully, which is facilitated by slightly warming the tar.

The gas liquor is composed of a great number of ammonia compounds for the

enumeration of which reference may be made to the technical literature cited on page 152. The volatile ammonia compounds can be partly driven off from the gas liquor by passing steam through it. The balance of the ammonia is combined with acids in the form of so-called "fixed" ammonia salts which require decomposition by lime before rendering the ammonia volatile in a current of steam.

The general arrangement of the ammonia plant for 100 coke ovens is shown in Fig. 5. It is arranged for the manufacture of both concentrated liquor and sulphate of ammonia. The crude ammonia liquor, which contains between 1 and 3% of ammonia (in accordance with the percentage of water contained in the coal and used in recovery) is pumped from the condensing house cisterns to the ammonia liquor supply tank *S*.

FIG. 5.—APPARATUS FOR MAKING CONCENTRATED AMMONIA LIQUOR AND AMMONIUM SULPHATE.

For the manufacture of concentrated ammoniacal liquor, the liquor from supply tank *S* is run in a constant stream into the preheater *A*, in which it is heated by the ammoniacal vapors and steam given off by the still. The hot liquor enters into the upper part of the volatile ammonia still *B*, where all the volatile ammonia is driven off; it then passes through the lime chamber *C* and lime still *D*, in both of which the fixed ammonium salts are decomposed, the solution finally leaving the lime still at *c* as spent liquor, which should contain but traces of ammonia. The reaction may be expressed as follows:—

The distillation is performed by means of steam, which enters the bottom of lime still *D* and of lime chamber *C*. Milk of lime is introduced into the lower

part of the lime chamber *C* through pipe *e*. The ammonia vapors and steam pass upward through the still proper, breaking in each section through the light seal of liquid, thereby heating the same and driving off the ammonia, until after leaving the upper section of still *B* they enter into the heater *A*, in which they preheat the fresh liquor coming from the supply tank *S*. From the heater the mixture of ammonia vapors and steam, together with volatile impurities (carbonic acid, hydrogen sulphide, etc.) pass through a large pipe line *A* into the concentrator *E*, in which they are condensed by means of cooling water. The ammonia vapors are absorbed by the water and a concentrated liquor is formed, which runs into storage tank *T*. The strength of the liquor can be regulated by the quantity and temperature of the steam used in the stills. The concentrated liquor is forced by means of air compressors into steel tank cars for shipping.\* The very obnoxious waste gases are brought into the poor-gas mains, and burned under the ovens, or otherwise disposed of in an inoffensive way.

For the manufacture of ammonium sulphate the process is identical with that of concentrated ammoniacal liquor with this difference that the mixture of steam, ammonia vapors and volatile impurities, after leaving the heater *A* are conducted, instead of to the concentrator *E*, to the saturators *F*, which are filled with diluted sulphuric acid. In these saturators, ammonium sulphate is formed with a considerable heat.

When the sulphuric acid becomes neutralized, the ammonium sulphate separates in the form of white crystals. The salt and mother liquor are finally dropped from the bottom of the saturator into the cooling tank *G* and another saturator is placed in use. After all the ammonium sulphate has crystallized out, it is put through a centrifugal dryer *H*, from which the mother liquor flows into the well *L* and the dried ammonium sulphate drops from the bottom upon a belt conveyor *K*, which brings the market product to the storage room or to the apparatus for automatically weighing it and placing it in bags.

The waste gases from saturators *F* pass through waste gas pipes into the poor-gas main in the same manner as in the manufacture of concentrated liquor. It is necessary, in running the saturator, to cut off the supply of ammonia gas before the point of saturation is reached otherwise loss of ammonia and discoloration of the ammonium sulphate ensues.

#### WORKING RESULTS OF A PLANT OF 100 OTTO-HOFFMANN COKE OVENS.

It is difficult to give a working statement which will apply to all conditions, as the latter may vary considerably with the location. The following items, however, enter into the actual working results and give sufficient data to enable an estimate to be made for any particular condition:—

---

\* For the effect of the concentrated ammonia on steel tanks see Pennock & Morton, *Journal of the American Chemical Society*, 1902, XXIV., p. 877.

tion of tar and its per capita production is even less than that of France. Therefore a large increase in the tar production would not be by any means so serious a matter as has been feared by those averse to the by-product coking system. It is of interest in this connection to glance at the amount of tar and pitch imported into this country, as given by the Bureau of Statistics of the United States Treasury Department.

IMPORTS AND EXPORTS OF COAL TAR AND PITCH IN THE UNITED STATES DURING  
1895 TO 1901, INCLUSIVE.

| Year ending June 30th.        | 1895.    | 1896.    | 1897.    | 1898.    | 1899.    | 1900.    | 1901.    |
|-------------------------------|----------|----------|----------|----------|----------|----------|----------|
|                               | Barrels. | Barrels. | Barrels. | Barrels. | Barrels. | Barrels. | Barrels. |
| Imports of tar and pitch..... | 118,630  | 141,515  | 111,526  | 88,608   | 25,049   | 74,385   | 87,969   |
| Exports of tar.....           | 22,773   | 16,865   | 17,640   | 19,816   | 36,908   | 36,536   | .....    |

The imports and exports of tar are insignificant when compared with the production, particularly in recent years.

Of the 74,385 bbl. of tar imported into the United States in 1900, 71,980 bbl. came from the United Kingdom. The extent to which the other derivatives of coal tar are imported into this country is also to be taken into consideration. These products, comprising benzol, toluol, carbolic acid, salicylic acid, aniline and alizarine colors and dyes, and numerous other technical and pharmaceutical articles, were imported to the value of \$6,773,152 in 1900, on which duty to the amount of \$1,516,689 was paid.

The English market reports as given in the *Journal of Gas-Lighting* show that the average annual price of tar has varied from 1·57c. to 2·27c. per U. S. gal. since 1895, the average price for 1901 being 1·74c., and that pitch has varied from \$5·73 to \$10·47 per short ton; the average price for 1901 being \$8·49. The prevailing price for the tar in the United States ranges between 2·5c. and 3·5c. per gal. in large quantities. The German prices are somewhat above the English prices, and approach the American figures. Large quantities of crude tar products are imported by Germany from England. Germany, as is well known, leads all other countries in the manufacture of refined tar products, as is instanced by the fact that one-third of the crude carbolic produced in England is sent to Germany for refining.

*Composition*—Crude tar varies considerably in its quality, the differences arising partly from the coal from which it is derived and partly from the method of distillation. The distinguishing characteristic of coke oven tar is its low percentage of free carbon, which varies from 8 to 15%, while tar from gas works commonly has from 20 to 35% and even more, due to the higher heat used in carbonization which tends to destroy the hydrocarbons. The low percentage of free carbon in coke oven tar increases its value for most purposes, especially in the chemical industry. Characteristic analyses of coke-oven tar and gas-house tar are given in the table on page 154.

*Uses*.—Crude tar is used directly without further treatment for a number of purposes and a certain proportion of the production is absorbed in supplying these demands. A number of the smaller gas works, particularly in England and the United States, find disposition for their whole product in local fields for

(a) White & Hess, in *Journal of Chemical Industry*, 1900, p. 509.

painting, varnish making, pipe coating, dipping paving brick and roofing tile, preserving stone work, concrete pavements, etc. The manufacture of tar varnish consists principally in heating the tar to drive out the ammoniacal liquor, which would corrode iron work, and in thinning the tar by the addition of oil. The market for this product is limited, as a similar article, usually better adapted to its specific purpose, is made by the large tar works, by mixing hard pitch and light oils with other ingredients to suit various requirements. A certain amount of crude tar is also used for the basic lining of Thomas and Gilchrist steel converters, but the consumption in the United States for this purpose is very small. The use of crude tar as a fuel is also met with from time to time. Market conditions and the difficulties of transportation have in times past caused the burning of a great deal of tar, but of late years the development of the tar industry has precluded this. Numerous determinations have been made of the fuel value of tar for steam raising and other purposes. The theoretical calorific power of tar compared to coal was estimated by Mr. F. G. Dexter as 2 to 1.<sup>10</sup> Lunge<sup>11</sup> considers this value high and cites a test by Mr. J. T. Lewis, showing a ratio of 7 to 5 between tar and coke burned under gas retorts. Körting<sup>12</sup> gives the theoretical value as 1 to 1.2 but states that the practical efficiency will favor the tar. Mr. C. F. Prichard<sup>13</sup> gives the calculated calorific power of coal tar as 15,781 B. T. U. per lb. and coal as 14,385 B. T. U., a ratio between the theoretical values of about 1.1 to 1, while the actual test showed that the evaporative effect was as 11.91 to 9.8, a ratio of 1.21 to 1. The latter test Mr. Prichard does not consider as conclusive for the tar, but he believes that a ratio of 14 to 9.8 or 1.43 to 1 should be easily attained. This is practically the same as Mr. Lewis's ratio of 7 to 5 (1.4 to 1).

Tar (or preferably tar oil) when burned in a specially constructed furnace with insufficient air supply yields lamp black. The products of combustion are led through long brick passages before reaching the stack, and in these the soot is deposited. Lamp black is used in the manufacture of printers' and lithographers' ink, patent leather, and in making carbon electrodes.

Saturated felt paper is made by passing dry felt through hot tar, then through squeezing rollers, and then winding it up in rolls of the desired size, which are allowed to dry out before placing on the market. Felt, according to its nature and to that of the tar, will absorb from 75 to 150% of its weight. Two- and three-ply papers are made by passing two or three layers of saturated felt between heated rolls, at the same time adding hot pitch of the proper consistency to cement the inner surfaces together. Some papers are even supplied with a layer of gravel imbedded in pitch on one side, and are called "ready roofing." The saturated felt is usually applied to the surfaces to be water proofed, in successive layers, each being painted with hot pitch, which cements the whole together. If used on roofs a final layer of gravel is spread over the surface. For water proofing brick work or concrete foundations, the outer shell of the structure is built, and then lined with the saturated felt and well pitched, after which the inner masonry is built up.

*Coal Tar Distillation.*—Coal tar is ordinarily distilled by heating it in steel vessels enclosed in brick work settings which are provided with grates for burning coal. The vapors given off are condensed in a coiled pipe or worm immersed in water. The distillates flow into a small receiving tank which discharges into storage tanks provided for the different fractions; the oil usually being separated in accordance with its specific gravity. The pitch remaining is transferred from the still to a cooler, from which it flows into barrels when cooled to the proper temperature. The usual form of still is a horizontally-placed cylinder of boiler plate. The larger ones hold about 10,000 gal. and the smaller ones are of various capacities down to 500 gal. European tar distillers generally use a vertical still with concave bottom. In American practice the distillates given off below 270°C. (518°F.), are usually separated into light and heavy oils only (*i.e.*, oils of a lower or higher specific gravity than water). With the light oils, a more or less considerable amount of water is expelled, so they are collected in a storage tank and separated after settling. It is not usual to separate the fractions more carefully, though in some cases redistillation of the light oil for "naphtha," etc., is carried on. The heavy oils or creosote oils are used largely in wood impregnation, and for the manufacture of lamp black.

In European works, the distillation is carried much further, *i.e.*, to a higher temperature than in the American plants, the object being to obtain the anthracene oil, which is the basis of the very extensive alizarine dye industry. The following scheme of the distillation process is given by Schilling.<sup>14</sup>

| Temperature of Distillates.        | Commercial Product.                                                          |
|------------------------------------|------------------------------------------------------------------------------|
| I. Fraction up to 338° F. ....     | Ammoniacal liquor, 90% benzol, 50% benzol, solvent naphtha, burning naphtha. |
| II. Fraction 338° to 446° F. ....  | Naphthalene, carbolic acid.                                                  |
| III. Fraction 446° to 518° F. .... | Creosote oil for impregnation, lubricating oil.                              |
| IV. Fraction 518° F. upwards. .... | Anthracene                                                                   |
| V. Residue. ....                   | Pitch.                                                                       |

In European works the distillation is usually carried on under a slight vacuum, and the separation of the various oils is done by a measuring device. The temperature is carried as high as 360°C. (680°F.), which is about as high as the

<sup>14</sup> *Gas-Beleuchtung*, p. 226.

stills will stand. The resultant pitch which is much harder than the American product is run into depressed pitch floors to cool and is afterward broken up into pieces for shipment in bulk. It is chiefly used in the briquette industry. If a soft pitch is required, the hard pitch is remelted (or "cut back") with heavy oil, or the heavy oil is added to the pitch while it is yet molten in the still. A large portion of the soft pitch used in England and on the Continent is made in this way.

Numerous attempts have been made to avoid the difficulties incident to the operation of the ordinary intermittent tar still by developing a continuous process and a number of devices for the purpose are mentioned by Lunge in his work, *Coal Tar and Ammonia*, p. 334, of which those introduced and operated by Lennard in England, and H. Hirzel at Leipzig, appear to have met with some measure of success. The Lennard still, of which in 1895 there were three in Great Britain and one on the Continent, has a capacity as high as 480 bbl. per day.

*Soft pitch* is extensively used in paving to fill the interstices in brick, stone or wooden pavements. It is also used in asphalt pavements to some extent. Pitch by itself is very much used in certain sections of the country as a binder for concrete, and gives very general satisfaction where traffic is not too severe. A form of pavement called tar macadam has lately come into prominence. It is a combination of broken stone and soft pitch mixed hot and rolled in place under a heavy roller. Very good results have been reported from its use.

*Briquetting.*—The manufacture of fuel briquettes is the principal use for coal-tar pitch in England and on the Continent. The high price of fuel and the fact that there are large quantities of fine coal of little or no value has caused this development. The subject has been thoroughly discussed in *THE MINERAL INDUSTRY*, Vol. VI., to which reference should be made. It is possible that the increase in the number of by-product coke ovens and the consequent larger supply of tar and pitch, together with the growing demand for a convenient and smokeless fuel may cause the industry to make more progress in the United States than it has done hitherto.

*Tar Chemicals.*—The chemicals recovered from tar distillation are the benzols (50 and 90%), solvent and burning naphtha, pyridine basis, carbolic and cresylic acid, naphthalene, creosote oil, anthracene, etc. The development of the tar chemical industry has been carried farther in Germany than elsewhere, and the concerns engaged in it have been very prosperous.

#### AMMONIA.

*Distribution of Nitrogen in Products of Dry Distillation of Bituminous Coal.*—The nitrogen contained in bituminous coal is the most important source of ammonia, and in the near future it will doubtless become the most important source of combined nitrogen. Dr. Knublauch<sup>1</sup> found the distribution of

<sup>1</sup> *Journal fuer Gasbeleuchtung*, 1895, p. 756. Similar investigations are published by Wm. Foster, *Journal of the London Chemical Society*, 1893, p. 105, and L. T. Wright, *Journal of Gaslighting*, Vol. LII., p. 163, in which latter publication the great influence of the temperature is shown. H. Tichauer, *Journal fuer Gasbeleuchtung*, 1894, pp. 363 and 361.

nitrogen in the products of dry distillation of two Westphalian coals to be as follows:—

DISTRIBUTION OF NITROGEN IN PRODUCTS OF DRY DISTILLATION OF WESTPHALIAN COALS.

|                                                      | I.    | II.   |
|------------------------------------------------------|-------|-------|
| Of 100 parts nitrogen in the coal were found:        | %     | %     |
| In coke.....                                         | 30.0  | 35.6  |
| In gas liquor as ammonia.....                        | 11.9  | 14.1  |
| In cyanides.....                                     | 1.8   | 1.8   |
| In tar.....                                          | 1.3   | 1.4   |
| As free nitrogen in gas and rest not determined..... | 55.0  | 47.1  |
| Total.....                                           | 100.0 | 100.0 |
| Nitrogen in the coal.....                            | 1.55  | 1.479 |

It is therefore seen that only about 13% of the total nitrogen in the coal is obtained in form of ammonia. The Mond producer gas process recovers a part of the large percentage of nitrogen remaining in the coke.

The percentage of nitrogen in coal varies from 0.5% to 2.5%, and ordinary coking and gas coals contain from 1.5% to 2.0%.

A large number of processes have been suggested for the increase of the ammonia yield in the dry distillation of coal, among which the addition of lime to the coal has been proving advantageous, as far as the increase in the yield is concerned. Its use, however, is coupled with serious disadvantages which have prevented its adoption in practice.

*Gas Liquor.*—The amount of gas liquor obtained varies between 7% and 15% according to the percentage of moisture and water of decomposition as well as with the amount of additional scrubbing water used. It does not contain any ammonia in the free state, but is a mixture of various compounds in widely varying percentages of mixture. As an example of its composition the analysis of an English gas liquor is quoted from Arnold, *Ammonia and Ammonia Compounds*, which however should by no means be considered as an average analysis.

ANALYSIS OF AN ENGLISH GAS LIQUOR (BY DYSON).

|                             |                                                               |        |

| Total sulphur.....          | S                                                             | 0.898% |

A few of these compounds are decomposed by steam (volatile ammonia), ammonium carbonate, for instance, splits up as follows:—

Others are decomposed only by an addition of a stronger base than ammonia. For instance, ammonium chloride reacts with lime as follows:—

The relative proportions of fixed and volatile ammonia vary considerably, according to the character of the coal from which the gas liquor is derived.

**Crude Gas Ammonia Products.**<sup>2</sup>—The quantity of the various ammonia products concerned in the United States is given elsewhere in this section. Ammonia is stripped from the coke works generally as ammonium sulphate or concentrated ammonia liquor which form the basis for the production of the other ammonium compounds. Gas works in the United States generally sell the gas liquor in its crude state.

**Ammonium Sulphate.**—Ammonium sulphate is a white salt produced by passing ammonia vapors through sulphuric acid. The commercial article contains between 24 and 25% of ammonia ( $\text{NH}_3$ ), or from 19.8 to 20.6% nitrogen; its purity depends chiefly on the purity of the sulphuric acid used.

The coke-oven sulphate is very pure and is generally sold on a guarantee of 25% of ammonia ( $\text{NH}_3$ ). It is very hygroscopic and consequently has to be stored in dry places. It is usually shipped in bags of 200 lb., and in the manufacture care must be taken that there is no excess of free acid in the salt which would quickly destroy the bags. It is used chiefly as a fertilizer and as raw material for other ammonia products. The presence of small amounts of impurities (iron and cyanides, metallic sulphides, etc.) often causes more or less discoloration of the otherwise white or grayish salt. This is the cause of (unfounded) objection by the manufacturer of chemicals, while the color makes no difference to the manufacturer of fertilizers. In case the sulphate is to be used for the manufacture of anhydrous ammonia it should contain as little of pyridine and other tarry impurities as possible. Formerly ammonium sulphate was often made by neutralizing the gas liquor with sulphuric acid and evaporating the weak sulphate solution. This salt was very impure and contained more or less ammonium sulphocyanide, which is very objectionable in case the sulphate is used as a fertilizer, because it is poisonous to plants. With the manufacture of ammonium sulphate as now practiced, viz., by distillation of the crude liquor, the presence of this substance is completely avoided.

**Concentrated Ammonia Liquor.**—Concentrated ammonia liquor is produced by condensing the mixture of steam, ammonia and gases which are leaving the ammonia still. It is chiefly a solution of ammonium carbonate and ammonium sulphide and is generally guaranteed to contain a minimum of 15% of ammonia, but the percentage of ammonia varies between 15 and 20%. It is shipped in tank cars and is used chiefly in the manufacture of soda from salt (brine) by the ammonia process. It is also used as a raw material for the manufacture of other ammonia products and its use for this purpose may increase considerably, because it can be bought cheaper than sulphate on account of the saving of the expense for sulphuric acid. For many years there has been a great scarcity of ammonia in this country, which accounts for the slow development of the manufacture of soda, but with the increasing ammonia supply this industry has rapidly developed.

<sup>2</sup> THE MINERAL INDUSTRY, Vol. VII., "Ammonia and Ammonium Sulphate," by Mr. H. A. Frasch; Dr. G. Lunge und Dr. H. Koehler, *Die Industrie des Steinkohlentheers und Ammoniaks*, Fourth Edition, 1900, which has been translated into English; Dr. G. Lunge, *Coal Tar and Ammonia*, Third Edition, 1900; Dr. B. Arnold, *Ammoniak und Ammoniakpræparate*, 1880, translated into English, *Ammonia and Ammonium Compounds*; A. Fehrmann, *Ammoniakwasser*, 1887; Camille Vincent, *Ammonia and its Compounds*, 1901; Weill-Götsch et Desor, *Eaux Ammoniacales*, 1899; P. Truchot, *L'Ammoniaque* (without date).

In this connection the following list<sup>3</sup> of soda manufacturers, which does not include those making this product electrolytically, may be of interest:—

SODA WORKS IN THE UNITED STATES USING THE AMMONIA PROCESS.

| <b>Total</b> .....                             |                      | ..... 1,980                          |

Lunge<sup>4</sup> states that the loss in the manufacture of 100 tons of soda ash is about one ton of ammonia expressed as sulphate. Consequently the manufacture of 2,000 tons of soda ash per day would consume daily the equivalent of 20 tons of ammonium sulphate. We may estimate, therefore, the annual requirements of this country in the soda industry as equivalent to about 6,000 short tons of sulphate.

*Caustic Ammonia or Aqua Ammonia.*—This is produced by redistilling the concentrated gas liquor and removing all the impurities (carbonic acid, hydrogen sulphide, tarry constituents, etc.). It is therefore a concentrated solution of pure ammonia. It contains from 20 to 35% of ammonia (NH<sub>3</sub>). Formerly it was extensively used for refrigerating purposes, but it has recently been replaced to a great extent by liquefied anhydrous ammonia. It is now used in the textile industries for dyeing, for domestic purposes, for electroplating, for chemical purposes, in laboratories, etc. The price varies according to strength and purity. No statistics are available of the quantity of ammonia consumed in this form. It is generally shipped in iron drums of about 1,000 lb. capacity.

Considerable quantities of caustic ammonia are used in the manufacture of potassium cyanide by means of recent processes,<sup>5</sup> one of which has been introduced into this country, and a very considerable amount of ammonia is consumed. In Germany anhydrous ammonia is used instead of caustic, which is preferable for many reasons, but the present price of anhydrous ammonia makes its use for this purpose in the United States too costly.

Aqua ammonia often contains up to 2.5 g. pyridine per liter, which becomes troublesome in making anhydrous ammonia from it. Its determination is described by J. D. Pennock and D. A. Morton.<sup>6</sup>

*Anhydrous Ammonia.*—Ammonia gas is produced commercially, either by the distillation of concentrated ammonia liquor, in which case lime and copperas are added in order to retain the carbonic acid and hydrogen sulphide and subsequent cooling, purifying and drying of the ammonia gas, or by the decomposition of ammonium sulphate with caustic lime under heat:—

<sup>3</sup> *Chemical Trade Journal*, Jan. 18, 1902.

<sup>4</sup> *Manufacture of Sulphuric Acid and Alkali*, Vol. III., p. 121.

<sup>5</sup> *Journal of Franklin Institute*, 1902, p. 72.

<sup>6</sup> *Journal of the American Chemical Society*, 1901, p. 385.

The ammonia gas is carefully freed of moisture and all impurities and is then liquefied by compression. It is generally shipped in iron flasks holding about 100 lb. each. It has been found that anhydrous ammonia manufactured from coke oven sulphate contains but very little of the undesirable pyridine bases. The present price of anhydrous ammonia is about 25c. per lb. f. o. b. ammonia works. According to *United States Census Bulletin* No. 174, p. 9, the price during 1900 varied from 22 to 40c. per lb. (on an average, 26·4c.), according to the distance from the source of supply. It is chiefly used for refrigerating purposes and in the manufacture of artificial ice.

*Refrigeration and Ice Manufacture in the United States.*—Artificial refrigeration has developed in the United States to an astonishing degree, so that this industry has become the outlet for large quantities of ammonia. A number of processes have been invented which were based upon the use of materials other than ammonia, i.e., sulphurous acid, ether, etc., but they have been unable to compete with the ammonia process, which is operated either by the compression system, using anhydrous ammonia, or the absorption system, using aqua ammonia.

Artificial refrigeration is used for the manufacture of ice and for the production of cold in breweries, meat and provision packing houses, chemical factories, etc.

The combined capacity of all refrigerating and ice-making machinery in the United States is estimated at 200,000 tons of refrigeration per day. This estimate has been based upon the numbers and size of the machines built by the various manufacturers.

The loss of ammonia varies considerably, but we may assume as an average figure 20 lb. ammonia ( $\text{NH}_3$ ) per annum for each ton of daily refrigerating capacity (40 lb. per ton ice-making capacity). On this basis the present annual requirements are equal to 2,000 short tons of ammonia (or 8,000 short tons ammonium sulphate).

The *United States Census Bulletin* No. 174 gives interesting statistics compiled by A. L. Hunt on the manufacture of artificial ice, which constitutes only a part of the refrigerating capacity of the United States. Nevertheless they may well be taken as an index of the growth of the refrigerating industry:—

(a) United States Census statistics.

This development is especially noteworthy in that the progress in the Northern States indicates that artificial ice is now successful in its competition with natural ice.

The amount of ammonia consumed is given at 1,056,535 lb. anhydrous (costing on an average 26·4c. per lb.) and 1,323,454 lb. aqua (costing on an average 6c.

per lb.). Taking the latter at 20% ammonia ( $\text{NH}_3$ ) we would find that the total ammonia consumption has been equivalent to 660 short tons anhydrous (or 2,640 short tons ammonium sulphate) in the manufacture of ice alone. The ice production during 1900 was 4,294,439 short tons. Calculating from these figures the annual ammonia consumption for each ton of ice-making capacity per day is 112 lb., which figure is considerably higher than that found above in the computation of the refrigerating ammonia consumption in the United States. It must be borne in mind, however, that these ice plants comprise the majority of the smaller and less economical works.

*Other Ammonium Compounds.*—The following ammonium compounds are of commercial importance: Ammonium chloride (muriate of ammonia), ammonium carbonate, ammonium nitrate, ammonium picrate, ammonium sulphocyanide (rhodanate of ammonia), and ammonium phosphate. Also, but of minor importance, ammonium chromate, ammonium acetate and ammonium oxalate.

*Sources of Ammonia Supply.*—The domestic ammonia production of the United States until recently has been derived almost entirely from coal gas works, but this supply is becoming entirely inadequate. In recent years by-product coke ovens have been adopted and there are fair prospects of their rapid introduction. This is the only source of domestic ammonia supply which promises a considerable increase.

In England ammonia has also been recovered from the Mond gas producers, from the shale-oil industry, and from certain blast furnaces operating on bituminous coals. Small quantities are also obtained in abattoirs and bone charcoal factories. No great increase may be expected from these sources. The largest part of the world's production of ammonium sulphate is used as a fertilizer, a field in which enormous quantities of sodium nitrate are consumed. The addition of the statistical data for the latter may therefore prove of interest.

The following table shows the world's production of ammonium sulphate and exports of sodium nitrate from Chile, the latter being practically identical with

WORLD'S PRODUCTION OF AMMONIUM SULPHATE AND SODIUM NITRATE. (a)

the world's production. This table shows (1) that the nitrogen equivalent of the sulphate production is only about one-half that of sodium nitrate. (2) That the production of sulphate has been constantly increasing even during the period when the price of its nitrogen equivalent was higher than that of nitrate. The progress will doubtless be continued.

*Production and Consumption of Ammonia and Nitrate in the United Kingdom.*—By reference to tables elsewhere in this volume it will be seen that the United Kingdom is the only exporting country; all others obtaining their deficiencies from Great Britain. This is for two reasons, viz.: (1) The consumption of gas per capita is larger than in any other country and almost all the gas is coal gas, which accounts for the large production of sulphate, and (2) the English farmer is slow in recognizing the value of ammonium sulphate as a fertilizer.

In both instances, however, there are movements on foot which tend to reduce the available surplus. Water gas is making rapid advances<sup>7</sup> and the domestic consumption of ammonium sulphate is also increasing, due to the energetic propaganda of the British Agricultural Stations and the Sulphate of Ammonia Producers' Association.

STATISTICS OF AMMONIUM SULPHATE PRODUCTION AND CONSUMPTION OF THE UNITED KINGDOM FROM 1895 TO 1901, INCLUSIVE. (a) (LONG TONS.)

(a) *Zeitschrift fuer Angewandte Chemie*, April 23, 1901, and *Bradbury & Hirsch's Review* for 1901, p. 23.

The statistics of sodium nitrate importations show that the consumption of the United Kingdom is slightly increasing, being 121,000, 126,000, and 126,000 long tons for the years 1899, 1900 and 1901, respectively.

*Production and Consumption of Ammonium Sulphate and Sodium Nitrate in Germany.*—Germany absorbs nearly 40% of the sodium nitrate exported from Chile, and in addition to this about 44,407 gross tons of ammonium sulphate were imported from England in 1901. There are now about 5,750 by-product ovens in operation, which yield 115,000 metric tons of ammonium sulphate per annum. The consumption of ammonium sulphate in Germany has increased from about 80,000 metric tons in 1893 to about 175,000 metric tons in 1901, an increase of about 120%. This increased consumption of sulphate has not by any means reduced the importation of nitrate, which increased from 371,000 metric tons in 1893, to 530,000 tons in 1901, or over 40%. The explanation of the increased demand for nitrogen in excess of the home production is that the thorough educational campaign by Agricultural Institutions has awakened an appreciation of proper fertilization. Prof. König estimates that of the 484,543 metric tons of sodium nitrate imported in 1900, nearly 75% was used for fertilizing purposes.

<sup>7</sup> *Iron and Coal Trades Review*, March 14, 1902, p. 639.

The present nitrogen consumption for fertilizing purposes in Germany (exclusive of animal and vegetable refuse), is 350,000 metric tons sodium nitrate, 15.5% = 53,250 metric tons nitrogen, and 100,000 metric tons ammonium sulphate 20.0% = 20,000 metric tons nitrogen, making a total of 73,250 metric tons of nitrogen.<sup>8</sup>

If all the German coke plants were equipped for the saving of by-products and all the ammonia were saved by the gas works, the following maximum ammonium sulphate production could be obtained at the present time:—

Coke Works.—Present production about 11,500,000 metric tons coke, which could yield annually, on the assumption of 75% coke and 1.15% sulphate results, 165,000 metric tons ammonium sulphate.

Gas Works.—Present production about 20,000 metric tons sulphate, which could be increased to 35,000 metric tons ammonium sulphate.

The maximum production could therefore not exceed 200,000 metric tons ammonium sulphate.

It is estimated that 40,000 metric tons of ammonium sulphate are required for miscellaneous purposes, which leaves 160,000 metric tons ammonium sulphate available for fertilizing purposes. The nitrogen equivalent of this last named quantity of ammonium sulphate is only 32,000 metric tons.

In other words, all the ammonia which could possibly be saved in the present state of the coke and gas industries would represent only 44% of Germany's present consumption of nitrogen in the form of sodium nitrate and ammonium sulphate for fertilizing purposes, and the wisdom of the German Government in acquiring sodium nitrate mines thus becomes evident.<sup>9</sup>

*Production and Consumption of Ammonium Sulphate and Sodium Nitrate in the United States.*—There are no exact figures obtainable, therefore only approximate estimates can be given. These however show the limited demand that exists here, especially when compared with Germany.

ESTIMATE OF AMMONIA SUPPLY AND CONSUMPTION OF THE UNITED STATES  
FOR 1901.

| Supply.                                            | Ammonium Sulphate Equivalent. | Consumption.                                                                                 | Ammonium Sulphate Equivalent. |

The following table of the production of ammonium sulphate in by-product

<sup>8</sup> Prof. P. Wagner estimates Germany's entire nitrogen consumption for fertilizing purposes at 100,000 metric tons, which undoubtedly includes the organic fertilizers.

<sup>9</sup> *Zeitschrift fuer Angewandte Chemie*, March 18, 1902, and *Engineering and Mining Journal*, March 22, 1902.

coke ovens has been given in *L'Engrais*, 1901, which shows a variation in the figures for the United States from the preceding table, which is due probably to the assumption that the new coke ovens were in operation during 1901. Most of them, however, will not be completed until late in 1902 or early in 1903.

PRODUCTION OF AMMONIUM SULPHATE IN BY-PRODUCT COKE OVENS IN 1901.

*Ammonia from Gas Works in the United States.*—The production of ammonia in gas works in the United States (equivalent to about 12,000 tons of ammonium sulphate per year) is increasing but very slightly owing to the extensive introduction of the water gas process, in which no ammonia is saved. Coal-gas works only are producing it, and practically all the larger works in this country are now equipped with ammonia stills.

The total amount of coal carbonized by gas works in the United States during 1901 is estimated at 2,100,000 short tons. In the large works with good practice, ammonia equivalent to 1.0% of sulphate is recovered, but in works of moderate size not more than from 0.6 to 0.8% sulphate equivalent is obtained. If an average yield of 0.8% be assumed, the possible maximum quantity of recoverable ammonia for 1901 would amount to 16,800 short tons sulphate equivalent. There were recovered 12,000 short tons during 1901, which leaves a waste of 4,800 short tons.

From these estimates it may be assumed that no increase in the manufacture of ammonia by gas works may be expected to an extent which could seriously influence the ammonia market.

*Ammonium Sulphate from Coke Works in the United States.*—The annual capacity of all the ovens now building and in operation may be estimated at 50,000 short tons of ammonium sulphate per year.

*Ammonium Sulphate from Abattoirs and Bone Carbonizing Works in the United States.*—A limited amount of second grade ammonium sulphate having about 19% nitrogen is produced in these works. Its price is from \$2.50 to \$3 less than gas liquor ammonium sulphate. The use of bone charcoal in sugar refineries is decreasing and no increase in the ammonia supply from these sources need be expected.

*Imports of Ammonium Salts.*—Since the introduction of by-product coke ovens the ammonium sulphate production has been nearly doubled. In the face of this the price has risen, and the imports, which were 16,822,090 lb. in 1890, were 28,971,761 lb. in 1901, an increase of 72%. This is due to its growing demand for refrigerating and fertilizing purposes, and the inadequacy of the domestic supply. The imports of ammonium chloride (muriate) and ammonium carbonate have been constantly decreasing as the domestic production can now supply the increase in demand. The imports of gas liquors, which were mostly from Canada, have ceased entirely. The tariff schedule has been responsible for some of the fluctuation in imports.

## RATES OF DUTY ON AMMONIUM SALTS IMPORTS INTO THE UNITED STATES.

|                                  | McKinley Tariff.<br>1890. | Wilson Tariff.<br>1894. | Dingley Tariff.<br>1897. |
|----------------------------------|---------------------------|-------------------------|--------------------------|
| Ammonium sulphate.....           | 0.5c. per lb.             | 20% ad valorem.         | 0.8c. per lb.            |
| Ammonium chloride (muriate)..... | 0.75c. per lb.            | 10% ad valorem.         | 0.75c. per lb.           |
| Ammonium carbonate.....          | 1.75c. per lb.            | 30% ad valorem.         | 1.5c. per lb.            |

*Prospects of Ammonia Supply.*—From the foregoing it is plain that there is no prospect of any important increase in the ammonia from gas works and abattoirs, the only chance of increase in domestic supply being from by-product coke ovens. The extent to which this may be relied on may be estimated from the total quantity of coke produced in 1901, *viz.*, 20,533,348 short tons. If this were coked in by-product ovens about 27,500,000 short tons of coal would be required, which on an average yield of 1% would mean only 275,000 short tons of ammonium sulphate. To this may be added 25,000 tons from the gas works, making a total of 300,000 tons of ammonium sulphate, or 60,000 tons available nitrogen per year. Germany alone, with but two-thirds the population and smaller agricultural interests, uses 80,000 tons of nitrogen in the form of ammonium sulphate and sodium nitrate for fertilization, a quantity which exceeds by 20,000 tons the present possible capacity of the United States.

*Ammonium Sulphate as a Fertilizer.*—Plants remove from the soil certain elements which they assimilate and which are necessary for their growth. By continued removal of crops certain of these elements are exhausted, and unless they are replaced the richest soil will in time become exhausted. The three elements that are indispensable to plant growth, and without which even under favorable conditions and cultivation no satisfactory crop can be obtained are nitrogen, potassium and phosphorus. All commercial fertilizers derive their value from the proportion of these substances contained in available form. Nitrogen is by far the most important and the most expensive. The value of ammonium sulphate as a source of nitrogen is admitted, and the increased crop returns, after the cost of the fertilizer has been deducted, is a matter which has been conclusively demonstrated. In order to encourage agricultural progress in general and with this the proper use of fertilizers the United States Government has established agricultural experiment stations throughout the country, particularly in the East and South, where the land has already shown signs of depletion. The outcome of this intelligent propaganda will inevitably increase the demand for ammonium sulphate enormously. For a detailed discussion of the fertilizing action of ammonium sulphate recourse must be had to the literature of the subject.

*Other By-Products.*—There are, outside of tar and ammonia, other by-products saved in the coking operation (benzole and its homologues, cyanides, sulphur, etc.).

The points brought out in the preceding discussion may be briefly summarized as follows:—

1. The by-product coke oven industry is firmly established in the United States. A great number of ovens are now in operation and in course of construction, representing many millions of dollars of investment.
2. The coke has proved at least equal to the best bee-hive coke.

3. New coal fields have been opened for the manufacture of metallurgical fuel by means of the by-product coke oven.

4. Several plants have been erected by The United Coke & Gas Co. and others, which demonstrate on an extensive scale the feasibility of manufacturing a smokeless fuel for domestic purposes, etc., simultaneously with large quantities of an illuminating gas of high candle-power. These results open a large field for the erection of coke plants outside of the manufacture of metallurgical coke.

5. The production of tar and ammonia in the United States is very small and the consumption per capita falls far behind that of other countries, so that we may expect a ready disposal at remunerative prices of all by-products which can be saved. Since the introduction of by-product coke ovens the prices of tar and ammonia have increased instead of decreasing and the importations of ammonia have also increased.

6. The present tar production of the United States is disposed of mostly for industries which are less extensively developed in European countries (roofing paper and paving pitch). On the other hand, the tar consuming industries of Europe are hardly known in this country (briquette manufacture, chemical industries, etc.).

7. Even if all of the ammonia from coal carbonized now in the United States could be saved it would not be sufficient to meet the nitrogen requirements for fertilizing purposes. At present Germany consumes more nitrogen in the form of ammonium sulphate and sodium nitrate than is represented by all the ammonium sulphate which the United States could save.

## PROGRESS IN POWER PLANTS USING GAS PRODUCERS AND GAS ENGINES.

BY WILLIAM KENT.

IN the article "Fuel and its Economical Utilization," which I contributed to *THE MINERAL INDUSTRY*, Vol. VIII., mention was made of the recent use of gas engines as blowing engines for blast furnaces in European iron works, and of the use in gas engines of producer gas derived from the Dawson and Wilson producers in England, the Lencauchez producer in France and the Taylor producer in the United States. One of the former limitations to the general use of gas engines supplied by producer gas was that the producers designed to make gas for gas engines were almost exclusively restricted to comparatively expensive anthracite coal or coke. In 1897, however, Brunner, Mond & Co., at Norwich, England, erected a producer which operated successfully with soft coal slack. In conclusion the article stated that the prospect of the displacement of the steam engine by the gas engine was very unpromising, and a summary of the special field of the gas engine was given as follows:—

"The internal combustion engine finds its field in special locations and conditions, such as automobile carriages, small yachts and torpedo boats, small powers (1 to 50 H.P.) where the use of a steam boiler entails more trouble than a gasoline motor and in places where water is scarce or bad. The field of the gas engine will be greatly increased if fuel gas can be distributed cheaply, as may be the case when by-product coke ovens have been generally introduced; under this condition the gas engine may become a serious competitor of the steam engines in sizes up to 500 H.P. It is doubtful, however, if a large electric lighting and power plant of 10,000 H.P. can ever be built to run with gas engines as cheaply as with steam engines, with the modern appurtenances of coal handling machinery, mechanical stokers, economizers and superheated steam. One horse power per hour from one pound of Pocahontas coal is already within the possibilities of steam engine practice, a figure very close to the best gas engine records from anthracite coal gas. With the fuel consumption of steam engines reduced to this figure the only hope for a gas engine to become a serious competitor is that gas from retort ovens may be sold at a price below its fuel value—the expense of running the coke oven being paid by the coke and the valuable chemicals which are obtained from the tarry by-products and the ammoniacal liquor. Until this happens the steam engine will continue to be the machine for utilizing the greater part of the coal that is used for power purposes."

Shortly after the publication of *THE MINERAL INDUSTRY*, Vol. VIII., the Westinghouse Machine Co. and the Westinghouse Electric & Manufacturing Co. issued a pamphlet which gave an entirely different view of the prospects of the gas engine operated by producer gas. It was claimed that the three conditions essential to the general application of gas as a fuel for engine driving had been realized, namely, its generation, its distribution and its use, and that this being the case, the resultant development of power by gas engines would revolutionize the present situation; the gas engine would supplant the steam engine as the latter would then be too costly to maintain; the steam boiler would be used for heating purposes only, the steam being generated over gas furnaces; coal would be

supplied by gas for cooking and heating; gas lighting in cities and towns would be supplied by electric lighting from generators driven by gas engines, and street and elevated railways would also be supplied by generators driven by gas engines. The following is quoted from the pamphlet referred to above:—

"The existing demand for large electric power units for operating street railways has resulted in the installations of plants of the following general outline:

"A large central steam power and electric generating plant, the electric generators being of the multi-phase type for the generation of currents at high voltages, a high tension system of distribution to local stations, where there are step-down transformers, which supply alternating currents to rotary converters, which in turn feed direct currents to third rail or other circuits, for the operation of the motors on the cars.

"Coal can be made into gas of a satisfactory quality at gas works suitably located. The gas can be taken by pipes to gas engines placed in the positions corresponding to the sites of the rotary converters of the foregoing plan, for a capital expenditure below that required for an equivalent steam boiler and engine plant. The cost for fuel per electrical horse-power so delivered should not exceed 50% of the cost of the fuel for generating electricity by steam for similar service. At the present time projects for the electric equipment of underground, elevated and surface railways are everywhere discussed. The use of gas engines for developing the electrical energy, with suitable pipes laid for conducting the gas, would make the cheapest and most reliable system to construct and operate. It should be quite within the scope of the operations of existing gas companies to erect special gas works, put down special pipes, and supply gas for the operation of large unit gas engines in connection with such lines. The gas companies could avail themselves of the most recent processes for the generation of gas, many of which are well developed and understood."

On January 9, 1900, Mr. Westinghouse wrote a letter to the *New York Times* advocating the combination of the electric light and power companies in New York City, viz.: the Metropolitan, Third Avenue, and Manhattan Elevated Railways, the New York Gas and Electric Light, Heat & Power Co., and the United Electric & Power Co., with a view to unite in a common plan to provide the electricity needed in their operations. Mr. Westinghouse also mentioned the possibility of manufacturing fuel gas from garbage and soft coal which could be utilized to drive gas engines with electric generators, in this way excluding thousands of steam engines and boilers, which make a very considerable demand upon the water supply of the city. The gas engine control stations could be so located that the water needed for engine-cooling purposes would be derived from the river.

The above-mentioned pamphlet of the Westinghouse Co. and the letter were widely quoted in technical journals at the time, yet after the lapse of two years the huge electrical enterprises quoted by Mr. Westinghouse have installed steam boilers and engines, and in addition the New York Rapid Transit Underground Railway and the Underground Railways of London have contracted for a steam equipment. The Westinghouse Machine Co. has greatly enlarged its plant for the building of large steam engines and has further shown confidence in the future of steam by going to considerable expense in preparing to build the Westinghouse-

Parsons steam turbine. The company, however, has continued the development of the gas engine, and in April, 1902, it erected its first 1,000-H.P. gas engine for test in the same building in which it is constructing several 10,000-H.P. steam engines.

Taking up the discussion of the points set forth in the pamphlet of the Westinghouse Co., while it is true that the generation, distribution and use are the three conditions essential to the general application of the producer gas for gas engines, but little progress has been made along this line. The producer has been introduced to a limited extent but is still an expensive apparatus, costly to maintain and to operate. The distribution of gas in pipes is successfully accomplished in the transport of natural gas which has a heating value of 1,000 B.T.U. per cu. ft., and of illuminating gas, heating value of 640 B.T.U. per cu. ft., but it is an entirely different matter to distribute producer gas of only 125 B.T.U. per cu. ft., which to transport to a great distance would involve a high cost for piping.

As a thermo-dynamic machine the gas engine is far superior to the steam engine, as it turns from 50 to 100% more of the heat energy developed in its cylinders into mechanical work. To offset this advantage the gas engine is more bulky and costly than a steam engine of equal power and is more expensive to maintain. No gas engines larger than 1,000 H.P. have as yet been built in this country, while steam engines of 10,000 H.P. are becoming quite common. Furthermore the steam engine is being rapidly improved by the use of high pressure, high speed, poppet valves and superheated steam. Steam turbines of the de Laval and Parsons types are rapidly being introduced, both in the United States and abroad. A large contract for steam turbines has been given by the underground railways of London, but no large contracts for gas engines have been placed up to the present time.

The Otto Gas Engine Works<sup>1</sup> state that there is nothing new in gas engine practice worthy of special mention. This company has made no radical changes for some time, but has confined its attention to the perfection of minor details to bring the grade of the engine up to a high standard. As an example of the use of the Taylor anthracite gas producer with its engine is quoted the installation at the Erie railroad shops in Jersey City, N. J.

Westinghouse, Church, Kerr & Co.<sup>2</sup> state that while a number of their gas engines are successfully operating on producer gas, detailed efficiency tests have not been made. The general results obtained, however, indicate that the performance is very satisfactory and corresponds to a consumption at full load of not more than 1.25 lb. coal per brake H.P. per hour. The gas engine of this company develops a brake H.P. with from 10,000 to 12,000 B.T.U. per hour, and the producer builders generally guarantee to evolve from 75 to 80 cu. ft. of gas per lb. of coal, the gas having a calorific value of not less than 125 B.T.U.

R. D. Wood & Co., of Philadelphia,<sup>3</sup> builders of the Taylor gas producer, state that the economy of the gas engine and producer plant at the Erie railroad in Jersey City has been very satisfactory, although no test figures have as yet been

<sup>1</sup> Private communication. Jan. 18, 1902.

<sup>2</sup> Private communication, Jan. 23, 1902.

<sup>3</sup> Private communication. Jan. 21, 1902.

published. If the efficiency of the boiler be assumed to equal that of a producer (which as a rule is unfair to the producer) the thermal efficiency of the gas engine will be superior to the steam engine. Most engine builders guarantee 1.25 lb. coal per brake H.P. per hour, and one builder gives as low as 1 lb. coal per brake H.P. per hour. It is perfectly safe to guarantee 1.25 lb. coal per brake H.P. per hour, and the Westinghouse engine has made it on 1.17 lb. coal, including the steam for the producer. It is a question whether the steam engine can compare with this except under test conditions. While the gas engines and producer plants may exceed the cost of an equivalent steam plant, the economy of the former will readily offset the excess cost of 25% per year. The labor involved in running a gas plant will certainly not exceed that of an equivalent steam plant, and may be 75% of it or less. The repairs to a steam plant are not excessive, but it is reported that the equipment of the Erie railroad plant has involved a repair cost of less than \$100 for nearly three years. Inferior fuel may be used in the producer, but with good stoking there is less in this advantage than formerly except for special fuels.

#### PROGRESS IN CONSTRUCTION AND OPERATION OF GAS PRODUCERS.

*The Loomis-Pettibone Gas Producer.*—The Loomis-Pettibone Co., of New York, has made considerable progress in the introduction of a producer which makes gas from soft coal or wood. In construction it is of the double type, making alternately producer gas and water gas. These gases may be mixed in a gasometer for future use in gas engines. The following description and illustration are of a modern producer of this type. Figs. 1 and 2 showing the cross-section and plan of the Loomis-Pettibone gas producer and boiler, the two generators *A* and *B*, the vertical boiler *C*, the water-cooled valves *D* and *E*, the producer-valve *F*, the water-gas valve *G*. The generator is cylindrical in form and is constructed of iron and steel, the general dimensions being from 3 to 11 ft. in diameter and from 12 to 18 ft. in height. The lining is of fire brick, with fire brick arched grates, ash pit and boiler flue in the bottom. There is a door on top for charging and for the admission of air, also two cleaning doors above the grate and one below the grate, opening into the ash pit. In starting fires in the generators a layer of coke or coal about 5 ft. in depth is put in and ignited at the top, the exhauster creating a downward draft. When the body of fuel is ignited, coal is frequently charged, raising the fuel-bed to about 8 ft. above the grates, at which height it is maintained. Bituminous coal is generally used, being charged at intervals as needed, through the feed-door in the top of the generator. Air also is admitted through the same doors and is drawn down through the fresh charge of coal and then through the hot fuel-bed beneath by the exhauster. The resultant producer or generator gas is drawn down through the grates and ash pits of generators *A* and *B*, valves *D* and *E*, up through the vertical boiler *C*, valve *F* to scrubber and exhauster (valve *G* being closed), and is delivered into a small gas holder for supply to the furnaces. When the exhauster has brought the fuel up to incandescence the charging doors *H* and *I* are closed, valve *E* lowered, valve *F* closed, and valve *G*, leading to the water-gas holder, opened. Steam is then turned on into the ash-pit of generator *B*, and, in passing through the incandescent coal, is

FIG. 1. THE LOOMIS-PETTIBONE GAS PRODUCER AND BOILER.

decomposed, forming water gas. From generator *B* the gas passes through the connecting-pipe shown near the top of the generators, and down through the generator *A*. The gas passes through valve *D* into and up through the boiler *C*, and thence, after being washed in the scrubber, is conducted into a holder. Water gas is made for five minutes, when, the temperature of the fuel-bed having been considerably reduced, the steam is shut off, valve *G* closed, valves *F* and *E* opened, and the charging doors *H* and *I* opened. This process of making water and producer gas is alternated at intervals of five minutes or more, according to the quality of gas desired. In making the next run of water gas the course of the steam is reversed: *i.e.*, valve *D* is closed and the steam is turned into the ash-pit of generator *A*. Valve *E* is left open, but the other valves, *F* and *G*, and the charging doors, *H* and *I*, are operated the same as in the first case. The operation of a pair of generators of this type is exceedingly simple. A man with ordinary intelligence, even if he has had no previous experience in the manufacture of gas, would be competent with a week's practice to take charge and run the apparatus. As the valves are provided with hydraulic pistons, the labor is reduced to a minimum and only a few seconds are required to change from making one kind of gas to another. While the fires are being blasted and during the making of a run of water gas, the hot gases in passing through the boiler give up a large proportion of their sensible heat, which is converted into steam. This, in turn, is directed under the fires in the generators for decomposition. Another advantage of the double generator apparatus is that, as all gas is made to pass through the fire, the tarry matter from the coal is converted into fixed gases that can be conducted any distance through ordinary pipe and at any temperature or pressure. Again, as the steam is forced through two fires, the percentage of condensable water vapor is exceedingly small. The gas after passing down through the hot fuel-bed is free from tar and may readily be conveyed through pipes to any distance required.

Instead of making water gas in every alternate stage for the same length of time as producer gas, the generator may be worked on producer gas alone, steam being then admitted at various points while the exhauster is running and the operation of making producer gas is going on. It is, therefore, not requisite to alternate the action of the generators so frequently as every four or six minutes; but only so much water gas need be made as may be called for by the requirements of the work to which the process is applied. From the generating plant the producer gas is delivered to one holder and the water gas to another holder. From these holders the two gases pass to an especially designed proportional mixing valve, by means of which they are uniformly mixed in any proportion desired. From this mixing valve the mixed or power gas passes to the engines wherever located. The gas is fixed, clean, and free from tar and all impurities, can be conveyed in pipes to any distance, and will not foul the engine. The gas is also well suited to a large variety of industrial work in direct fired, semi-regenerative and regenerative furnaces.

*The Plant of the Moctezuma Copper Co., at Nacosari, Mexico.*—The plant of the Moctezuma Copper Co., owned by Phelps, Dodge & Co., of New York, was described by Mr. James Douglas at the meeting of the American Institute of

Mining Engineers in the City of Mexico in 1901. The special advantage of a gas plant in this district is on account of the absence of good fuel. The Loomis down current gas producer was modified so that both water gas and producer gas were made together by introducing steam into the producer continuously, which yielded a continuous production of mixed gas. When the fuel became too highly incandescent steam was introduced. The cost of wood at Nacosari is \$3, as compared with \$25 per ton of coal, and in many cases the wood gas produced was of better quality than the gas from coal. Typical analyses showed: Wood gas, 14% CO, 20% H, 16% CO<sub>2</sub> and 47.7% N; coal gas, 20% CO, 14% H, 8.2% CO<sub>2</sub> and 55% N. The power plant is described elsewhere in this volume under the section devoted to the review of copper mining in Mexico.

*The Plant of the Winchester Repeating Arms Co., at New Haven, Conn.*—The Loomis-Pettibone producer in use at this plant is at present being increased to double its former size. There are two gas mains about the works, one to convey the water gas and the other the producer gas. The water gas is used for drop forging, welding, brazing, annealing, tempering and for smelting fires. The mixed gases are used for annealing brass in large muffles and rotary annealing furnaces, lead melting furnaces and for direct fired furnaces. The mixed gases are also used for power purposes with gas engines. At present three gas engines are in operation, one of 95 H.P., one of 80 H.P., and one of 30 H.P. size. Three additional 165-H.P. Westinghouse gas engines are being installed for direct connection to electric generators. The current is used for power purposes having direct current motors located about the works.

*The Plant of the Detroit Mining Co., at Morenci, Arizona.*—This plant is similar to the one at Nacosari, and is located on the railroad between the smelter and concentrator. Gas is piped one mile to the smelters supplying two 200-H.P. three-cylinder vertical Westinghouse gas engines, each belted to a 120-K.W. alternating current dynamo. The dynamos operate in parallel and supply current to the motors and for lighting. A 60-H.P. Stockport gas engine operates the conveyors and briquetting machine, and a 60-H.P. Fairbanks & Morse gas engine runs an air compressor. The gas is piped 2,000 ft. to the concentrating mill, operating three 80-H.P. Otto-Crossley engines belted to a counter shaft which drives the two-unit mill. An addition of 800 H.P. of gas engines is being made to this plant.

*The Plant at Minas Teclotes y Anexas, Santa Barbara, Mexico.*—A 500-H.P. plant with four 140-H.P. Otto gas engines is being installed at these mines, which are operated by the Guggenheim Exploration Co.

From this information, furnished by the Loomis-Pettibone Co., it appears that the field for its producer in connection with gas engines has thus far been limited either to locations where coal is very expensive, as in Arizona and Mexico, or to places in which the gas can be conveniently used for other purposes as well as for gas engines, as in the case of the Winchester Repeating Arms Co., New Haven, Conn., where it is used for heating, welding, brazing, etc. The soft coal producer has not yet been introduced for running gas engines alone in any part of the United States where coal is moderately cheap, and there appears to be no prospect of its soon supplanting the steam boiler and engine in any large power plant.

The Mond producer seems to be making some progress in England, but only in connection with works for the production of chemical products from the distillation of coal. A company has been organized with \$5,000,000 capital to supply fuel gas to a district west of Birmingham, England, but it bases its expectation of profit on the market for ammonium sulphate, the gas being considered a by-product. The gas blowing engine, using the waste gas from blast furnaces, is making considerable progress in Europe but it has not yet been introduced in this country.

## COPPER.

THE production of copper during 1901 amounted to 597,443,212 lb., against 600,832,505 lb. in 1900, a decrease of but 3,389,293 lb. during the year, which was largely due to the efforts of the Amalgamated Copper Co. to corner the copper market. The output of its Montana mines was restricted, and certain Michigan mines were induced to co-operate with it to control the American copper market and to maintain the price of copper at 17c. These efforts resulted in disaster to the Amalgamated interests, for at the close of the year the market fell heavily, and the allied interests were left with large stocks of copper on hand. The output of copper for Montana during 1901 was 229,870,415 lb., against 254,460,713 lb. during 1900, a decrease of 24,590,298 lb. for the year, thus recording a production which was less than that of 1899. Michigan reported a considerable increase over 1900, with 155,511,513 lb., as compared with 144,227,340 lb. during 1900. In spite of an expected decline in the production of Arizona during 1901 that Territory increased its 1900 production by over 10,000,000 lb. Among the other States, Utah and California scored notable advances, while Colorado's 1901 production was very slightly more than that of 1900.

According to reports of American copper refiners, the amount of copper refined by electrolytic methods was approximately 80% of the total of 1901. The production of copper sulphate was 78,004,257 lb., compared with 78,218,478 lb. in 1900, while the average price for 1901 was 4.1c. per lb., as compared with 4.99c. for the previous year. Of the total production of copper sulphate in 1901 the amount recovered as a by-product was 51,000,000 pounds.

The stock of copper on hand at the end of 1901 was 209,587,698 lb., as against 93,050,230 lb. at the end of 1900.

The imports of copper during 1901, as reported by the smelting and refining companies and the United States Treasury Department were 176,472,369 lb., against 103,805,793 lb. in 1900, while the exports amounted to 227,194,184 lb., as against 352,731,143 lb. in 1900, showing a considerable decline. Foreign purchasers of copper adopted a hand to mouth policy, with a result that exports declined, and toward the close of the year the price of Lake copper fell so rapidly that the average for the year was but 16.55c. per lb., while the average for the first

nine months was 16·77c., against an average for 1900 of 16·52c. for Lake copper, and 16·11c. for electrolytic.

(a) This includes copper imported in low-grade Spanish and other pyrites chiefly for sulphur, and the copper imported from Canada in copper-nickel matte, in which the nickel is the metal of chief value; also the copper in certain gold and silver ores. These items did not until 1898 appear in the United States statistics of imports. (b) Including only the copper in sulphate obtained as a by-product in 1898. (c) Not including Mexican copper en route for Europe.

*Alaska.*—During 1901, the Pacific Coast Copper Co., capitalized at \$5,000,000, purchased from the Pacific Coast Mining, Milling, and Development Co., of California, 10 copper claims, of which five are on Copper Mountain and five near Summit Lake, Prince of Wales Island. Development work was begun during the latter part of the year. The mines are accessible to the coast and steamship transportation, and the ores consisting chiefly of chalcopyrite in iron ore, carry small values in gold and silver. The property of the Alaska Copper Co., comprising 18 claims, a tramway one mile long to the wharf at the harbor, saw-mill, buildings, etc., was sold to Spokane, Wash., parties during the latter part of the year. The ore consists of malachite and chrysocolla in a quartz gangue carrying as high as 30% Cu besides values in gold and silver. It is said that the ores can be concentrated into an 85% matte at one smelting at a cost of \$3 per ton. Prince of Wales Island is 140 miles long by 40 miles wide, and apparently the copper ores are generally distributed over it.

*Arizona.*—(By James Douglas.)—Despite an increase in production of copper of 10,779,898 lb., Arizona made less progress during 1901 than was expected. The Arizona Copper Co. closed its plant for six weeks during the reconstruction of its smelting works; the United Verde Co. reduced production in order to re-equip its principal shaft, and the serious drought in the southern portion of the Territory interfered with the operation of other producers. The conditions for the year 1902 afford promise of a somewhat increased output. The works of the United Verde Co. are equipped for active operations, and the Arizona Copper Co. is capable, with its new smelter, of making at least 26,000,000 lb. a year. The Copper Queen works were enlarged during the year, but it was not deemed advisable to urge them to their fullest capacity. The Old Dominion mine and

furnaces were in active operation during 1901 and although sulphides have been met with in the lower levels they were not in sufficient quantity to induce the management to make their mixed oxidized and unaltered ores into matte for concentration in the converter. The Old Dominion therefore is still the only concern which makes copper bars in quantity direct from the ore. The United Globe mines, and others in the vicinity of Globe, have been shipping a very moderate quantity. The Black Warrior Co. has erected an acid chamber and leaching plant, and has already commenced the extraction of copper on a working scale by sulphuric acid from the very siliceous ores of its mines. The result of its operations may have a notable influence on the method of treatment of copper ores in the Southwest, where there are large bodies of low siliceous oxidized ores.

Of the new companies the Calumet & Arizona Co. is building works at Douglas, in the Sulphur Spring Valley, to treat the ore which it has opened up in the Irish Mag mine, near Bisbee, and the Shannon Co. is erecting a 500-ton concentrator and smelting works of adequate capacity to treat the ores of the Metcalf and adjacent claims in the Clifton district. The Black Diamond Co. and other new producers may add somewhat to the total yield of the territory. The Copper Queen Co. is designing new works to be erected at Douglas, where ample space is available and abundant water flows at a shallow depth below the surface. With the exception of the Shannon Co. none of the new concerns is likely to produce during 1902. While there are no signs in any of the mines of Arizona to indicate exhaustion, none of the companies seems to be imbued with the ambition to force production and make high records. Arizona's output, therefore, in the future may be expected to show a moderate increase, but the policy of all the companies interested seems to be to keep production within the bounds of consumption, and not to allow ambition or rivalry to influence their conservative policy.

(a) Reported by producers direct to THE MINERAL INDUSTRY. (e) Estimated.

*California.*—The copper mining industry made good progress in 1901 as regards output and new developments and the outlook for the future appears encouraging. In Shasta County, which is the principal center of the copper industry, a large amount of prospecting and exploration work was done, and activity in this direction was also noticeable in other parts of the State, more particularly in Amador, Calaveras, Madera, Fresno, Mariposa, and San Bernardino counties. The Mountain Copper Co., Ltd., at Keswick, the largest producer in California, increased its output of matte and refined copper, although the ore tonnage from

its mines was considerably below that of the preceding year. The output of the Keswick smelter was 13,271 tons, this amount representing metallic copper in matte. From the year's operations a total profit of £380,144 was derived, out of which the sum of £250,000 was set aside for the reserve and depreciation fund, £125,000 paid in dividends, and £5,144 added to the surplus account. Especial attention was directed by the management to the location of new ore bodies and two discoveries were made that are now being explored. At the annual meeting of the stockholders in London a plan was proposed for the distribution of the accumulated surplus among the stockholders; the scheme as outlined involved the issuance of new shares to the amount of £250,000 and also the creation of debenture stock amounting to £750,000 and bearing interest at 6%. The latter is to be distributed among the stockholders and will be subject to future redemption out of the earnings and assets which may not be required for the company's operations. The De La Mar properties in Shasta County were transferred to the Bully Hill Smelting & Refining Co., a corporation organized under the laws of New Jersey. The output of the Bully Hill smelter during the latter part of the year, according to report, was about 350 tons of matte per month. According to reports by the State Mineralogist, the amount of copper produced during 1901 was 34,931,985 pounds.

*Colorado.*—The production in 1901 as reported by Hon. Harry A. Lee, Commissioner of Mines, was 7,872,529 lb., against 7,826,949 in 1900. More than one-half of the former total was contributed by San Juan and Lake counties. No new developments of importance were recorded except the construction of a smelter at Salida, in Chaffee County, which will have two furnaces for treating pyritic ores. The development of pyritic smelting in this State will be found in the article "Progress in Pyritic Smelting during 1901," elsewhere in this volume.

*Idaho.*—Favorable progress was made in the Seven Devils district, but as in previous years, the operations were limited mostly to construction and development work. It is expected that the railroad to Cuprum will be opened for traffic before the end of the present year, when the mines will commence to produce on a larger scale. The Boston & Seven Devils Copper Co. started construction on a 100-ton smelter at Weiser which, when completed, will treat the ores from the company's mines.

*Maryland.*—The Mt. Washington Copper Co., of Mt. Washington, shipped several carloads of ore during the year, to Newark, N. J., for refining. The ores are bornite and chalcopyrite, and contain small values in gold and silver. Considerable development work was accomplished, the old stopes and levels, abandoned since 1866, were cleared out and a new straight shaft started.

*Michigan.*—The output in 1901 was 155,511,513 lb., the largest recorded in the history of the State. The extension of operations by some of the more important producers, including the Calumet & Hecla, Quincy, and Osceola, was mainly responsible for the increase, although the contributions from the smaller properties and from the mines under development were notably larger than in preceding years. While the recent decline in copper prices doubtless will have an adverse influence upon the production of the new mines, all of the prominent companies, owing to their foresight in applying a portion of the increased profits

ing the last three years to developments and improvements, are in position to materially lessen the cost of producing copper. It may be assumed, therefore, operations will be continued by these companies on about the usual scale.

(a) Consolidated with the Osceola. (b) Consolidated with Mass. (c) Estimated.

The subjoined tables show the results obtained by the principal mines, their realization, profits and itemized costs of production for the period 1897-1901. Further information covering preceding years will be found in THE MINERAL INDUSTRY, Vols. I. and IX.

The Calumet & Hecla Mining Co. continued the extensive improvements to its mining and smelting plants which have been under way for some time, bringing near to completion at the end of the year. The new six-stamp mill designed for treating ore from the Osceola amygdaloid will have a capacity of about 3,000 per day, or 1,800 tons per day when working on the conglomerate ore. New tables are to be installed for concentrating the slimes, and a tailings bin 65 ft. in diameter and weighing over 500 tons will dispose of the waste material. The smelting works at Lake Linden were also partially reconstructed by the building of six new reverberatories to take the place of a like number of furnaces. The new furnaces are supplied with platforms on which the ore is loaded before being charged. The Osceola Consolidated Mining Co. did a large amount of development work in its mines, especially in the Osceola branch, where very productive ground has been found, and in the North Kearsarge, which

Prices obtained by taking the average prices realized by the other leading mines, including Quincy, Isale, Atlantic and Wolverine. (b) Computed from the shipments of freight over the Hecla and Torch roads. On this basis the yield in 1891 was 3.13% and in 1875, 4.30%.

(a) Sales of copper and interest. (b) Includes underground and surface expenses and costs of stamping. (c) Includes transportation to mill and surface expenses. (d) Not stated in the reports. (e) Not including interest. (f) Includes mining, transportation to mill, surface and stamping costs. (g) Fiscal year ending June 30. (h) Includes under mining costs. (i) Exclusive of interest and income from real estate. (k) Not including assessments. (l) Not deducting extraordinary construction account from annual profits.

now has an extensive equipment. No stoping was done in the South Kearsarge branch, although it is stated that a large amount of good ore was opened up during the year. Three of the four new stamps were erected and the whole capacity of the new mill will be ready for operation by the middle of 1902, when the old mill will go out of commission. Important savings of copper were effected by the new stamps which promise to materially reduce the cost of production when the mill is under full headway. The company was unfortunate last year in that it

adhered to the policy of holding its copper for 17c., with the result that much of its product had to be sold later in the year at a greatly reduced figure. The average price obtained was 13·9c., while other mines marketed their output at 16c. or more. The year's development of the Baltic mine has been highly satisfactory and in harmony with the general views that have been expressed by the management of the company. The average yield of copper per ton of rock stamped was 23 lb., compared with 19·58 lb. in 1900 and 17 lb. in 1899, while the output for the year was 2,641,432 lb., against 1,735,060 lb. in 1900. The first head in the new stamp mill was started in December and two more will be in operation by the middle of the present year. Underground the mine has been opened on a large scale, and when the improvements in the surface plant are completed, it may be expected that the Baltic Co. will become one of the leading copper producers in Michigan. The Tamarack Mining Co. reports for the year 1901 an average price of 14·22c. realized for copper during the year. The dividends were declared from surplus. The No. 5 shaft at the close of 1901 reached a depth of 4,938 ft. The Quincy Mining Co. paid from the earnings of 1901 in dividends \$1,000,000. Part of the year's earnings of \$1,424,542 were retained in the treasury to increase the surplus and to provide money for the erection of a coal unloading and storage plant, a new dock, and a railway extension at Torch Lake, all to be constructed during 1902. The Wolverine Copper Mining Co. is erecting a modern mill containing two heads of stamps which will have a capacity of 1,000 tons of rock daily, an increase of 50% over the capacity of the two small heads of stamps now in use. The new mill site is on Traverse Bay, the foundations are completed and structural steel work being put into place. The mill is expected to be in operation by July 1, 1902. During construction dividends have been limited to \$2 per share, payable half yearly. At the Atlantic mine the installation of a new "Ingersoll-Sargent" cross compound air compressor has greatly facilitated operations. Its capacity is 4,670 cu. ft. of free air per minute, at 75 lb. pressure, and at 75 revolutions per minute. New rolling stock was purchased for the railroad, enabling it to transport rock for the Baltic mine. The Mohawk Mining Co. has completed the structural work of its new stamp mill at Traverse Bay, and it is expected that it will be entirely completed by July, 1902. The 16-mile railroad connection between mine and mill is operated under lease, by the Hancock & Calumet R. R. During the latter part of the year, 170 tons of "Mohawkite" were shipped to the special reduction works at Newark, N. J. The net value per ton of this mineral did not approach that of the trial shipment to Swansea, Wales; \$75 per ton being the best net price realizable at the present value of copper. While the veins of "Mohawkite" persist with depth, they vary greatly in size and value. The new mill of the Adventure Consolidated Mining Co., for which the structural steel work was completed and the machinery nearly all on the ground in December, 1901, has three Allis-Chalmers stamps, fitted with coarse rock screens, round mortars, jigs, slime tables, and six Wilfley concentrators. The rock bins have a capacity of 4,500 tons equal to three days' supply. The Arcadian Copper Co., which has expended more than \$1,000,000 in development work during the past few years, has closed its St. Mary's shafts and confined its work to the old mine or Douglas shafts. The

Arnold Mining Co. has reduced its force to 12 men and has apparently abandoned hope of success in its mining operations. The Centennial Copper Mining Co. plans to erect a new mill of 2 heads of stamps at Torch Lake during 1902. The result of work on the Kearsarge Lode during 1901 has been so satisfactory that all work on other lodes has been indefinitely suspended. The Isle Royale Copper Co. started its new mill in May, 1901, and during the year stamped 185,175 tons of rock with a yield of but 11.75 lb. of copper per ton. Recent cross-cuts have resulted in the development at depth of the Grand Portage Lode at a distance of 200 ft. west from the Isle Royale Lode, which shows slightly better returns in copper than the latter. The cost of mining and stamping a ton of rock is \$1.863. Late in December, 1901, an important consolidation was effected resulting in the organization, with a capitalization of \$28,500,000, of the Copper Range Consolidated Co., which purchased for \$1,000,000 of its stock the Baltic Co., and for \$1,500,000 stock the Copper Range Co. Thirty-five thousand \$100 shares were offered to the public at \$40 per share and with the balance of the treasury stock such other mines as the Trimountain and Champion mines may subsequently be purchased.

*Montana.*—The production of the individual mines in this State, from 1895 to 1901, inclusive, is given in the subjoined table:—

COPPER PRODUCTION IN MONTANA. (POUNDS OF FINE COPPER.)

| Mines.                      | 1895.       | 1896.       | 1897.       | 1898. (d)   | 1899.       | 1900.       | 1901.       |

(a) In addition to 818,531 lb. of Canadian copper smelted by the Montana Ore Purchasing Co. and deducted in the above table, there was also deducted 1,000,000 lb. more of foreign copper estimated as having been included in the aggregate of the above returns, leaving the net amount 228,958,164 lb. (b) Included in reports of smelters itemized above. (c) Totals reported by E. B. Braden. (d) The individual reports include some copper derived outside of Montana, wherefore their sum exceeds the total as given. (e) Included under "Other Mines." (f) Estimated.

Prepared by George W. Winter.—The production of copper in Montana, during the closing months of the year, shows a heavy shrinkage due to the companies controlled by the Amalgamated Copper Co., the extensive repair work at the various properties on the hill partly accounting for the decreased production of copper. A drainage system has been established to have the mine water taken care of by two central points. At the 2,200-ft. level of the High Ore mine a pumping plant is being installed capable of handling 4,000 gal. in 24 hours. The Mountain Consolidated, Diamond, Green Mountain, Wake Up Jim, and the two Grey Rocks will be drained through the High Ore mine. At the 1,200-ft. level of the Leonard Shaft of the Boston & Montana Copper Co. a compound condensing pump (duplex) is being installed with a daily capacity of 1,000 gal. for that lift; this pump is intended to drain a large area of its territory, the 1,200-ft. level of the Leonard being connected with the two Colusa's, Piccolo, Comanche, Gambetta, and Mountain View mines. The works of this company at Great Falls

is being generally overhauled and enlarged and the improvements will be completed early in January, 1902. At Anaconda the upper works has gone out of commission, while the lower works is running at about two-thirds of its capacity. Work on the new Washoe smelter of the Amalgamated Co. is being completed. This plant, which is probably the most complete and modern in the country, will probably be in full operation by the spring of 1902. The smelter of the Montana Ore Purchasing Co., at Butte, was partially destroyed by fire in April, 1901; aside from the curtailment of output due to the fire, the works has been busy to its total capacity and two new converters have lately been added. The Butte & Boston smelter operated continuously during 1901 with the exception of about 30 days, when it was idle through labor troubles, its chief ore-supply coming from shafts No. 1 and No. 3 of the Silver Bow and East Grey Rock mines. The Colorado smelter also was idle for a short time from the same cause. A new roaster of an improved turret type, designed by Richard F. Pearce, is giving great satisfaction. The Parrot Silver & Copper Co., during the fall of 1900, lost through a fire their entire headworks equipment which was replaced during 1901. A steel gallows frame with a height of 100 ft. to the sheaves has been erected over the main shaft; the total weight of frame is 125 tons, with a safe load capacity of 50 tons. A first motion hoist, 28×96 in., inclosed in an engine house, and an iron compressor house, both of modern brick, stone, and iron construction, are among the improvements, the total cost being about \$250,000. Of the independent copper properties of the camp, the Speculator is the most important; during the year 200 ft. was added to the shaft, making it 1,400 ft. deep; 300 miners are employed; the property is operated as a close corporation, and can show a larger net profit than any other single mine of the camp, the net profits for the year approximating \$1,000,000. The Farrell Copper Co., one of the recent enterprises, has started three shafts on the flat, a short distance east of Meaderville, one of which has reached a depth of 600 ft. Two long-distance electric-power transmission lines bringing power from a distance of about 60 miles have their wires strung to Butte, ready for operation. The following statements of net profits were taken from the books of the county assessor, as returned by the various companies for the fiscal year ending June 30, 1901: Anaconda Copper Mining Co., \$5,571,815; Boston & Montana Con. C. & S. Mining Co., \$7,042,300; Butte & Boston Con. C. & S. Mining Co., \$586,055; Colusa Parrot Mining & Smelting Co., \$245,400; Colo. Smelting & Mining Co., \$303,620; Montana Ore Purchasing Co., \$1,250,000; Parrot Silver & Copper Co., \$510,195. The courts have been largely occupied with the various suits between the Montana Ore Purchasing Co. and the Amalgamated Copper Co., several new suits were instituted during the year, which have yet to come to trial. The properties of W. A. Clark and the Butte Reduction Works were operated continuously throughout the year. During the latter months of 1901 not to exceed 50% of the normal force of miners found employment in the mines of the Amalgamated Co., with the single exception of the Gagnon mine, which worked full handed, maintaining its maximum production, and possibly the Parrot, which also produced continuously.

*Nevada.*—Shipments of copper ore from Good Springs, Lincoln County, were made during 1901 by seven different mines, to the new terminus of the Eastern

California railway. The greatest depth thus far attained in any mine is 750 f., and at that depth no water is found. In Lyon County the Excelsior Copper Mining Co., operating the Bluestone mine, 5 miles southwest of Yerington, completed the erection of its 150-ton water-jacketed smelter. The ores of this mine are said to be copper oxide and carbonates, and average 10% copper. Early in 1902 the Nevada Consolidated Copper Co. will start work on a large scale on the McConnell mine. Many promising copper properties have been discovered in the new Tonapah district. The Nevada Copper Co., of Humboldt County, completed the erection of its 50-ton smelting furnace, early in 1901, and during the year made a number of shipments.

*New Jersey.*—The attempts made during the latter part of 1901 to operate the new plant of the Arlington Copper Co., at Arlington, proved unsuccessful from various causes, including difficulties in leaching. The plant is composed of the following machinery: One 350-H.P. Babcock & Wilcox boiler, with Kent regenerative fire-box; a 500-H.P. compound Erie City engine, connected direct to a 240-volt, 1,250-ampere, Crocker-Wheeler dynamo, switch-board, pumps, air-compressor, etc. All machinery is electrically driven, consisting of mine-hoist, No. 5 Blake crusher, one set of Allis-Chalmers rolls, two 10-ton per hour Kent mills, grading screens, and a Brown roasting furnace, 200×10 ft. hearth area, four 125-ton leaching tanks, and a 30,000-gal. stock solution tank. An acid-proof pump circulates solutions, and a series of 128 electrolytic cells connected in multiple, with lead anodes and cathodes, presenting about 6 sq. ft. of area each, are housed in a separate stone and steel building.

*New Mexico.*—Phelps, Dodge & Co. accomplished considerable development work on the Modoc mine, Grant County, during the year; elsewhere in the same county the Clifton Copper Co. completed and put in operation its new concentrating plant, which includes a crusher, a set of rolls, two Huntington mills, two Wilfley and two Standard concentrating tables. At Lordsburg the Lena Mining Co. completed its concentrator at an expense of \$100,000, and another Lordsburg company was erecting a smelting plant comprising two cupola furnaces, to be used either as lead or copper stacks. The Jura-Trias Co., of Bernalillo County, completed and put in operation its reverberatory furnace, and during the latter part of the year began the erection of another reverberatory. The product from the reverberatory operation consisted of two-thirds black copper and one-third white metal. This company mines its own coal. During the latter part of the year the Santa Fé Gold & Copper Co., of Santa Fé County, produced an average of 10 tons of matte per 24 hours, from ores averaging 4.75% copper, and silver and gold valued at \$1.50 each per ton. The cost of mining and smelting was \$7 per ton. The slag losses were less than 0.5% copper. The mine and smelter is 20 miles from the Atchison, Topeka & Santa Fe R. R., and wagon haulage of coke, etc., adds greatly to treatment charges. The Rio Hondo Copper Co. during the year began the construction of a smelter, and the Fraser Mountain Copper Co. started the construction of a concentrating plant and matting furnace.

*North Carolina.*—(By W. H. Weed.)—In the Gold Hill district, which between 1842 and 1893 produced over \$3,500,000 in gold, and was then abandoned owing to the presence of copper in the ore, the Union Copper Co. has made ex-

tended development. Its smelter was blown in September 20, 1901, and high-grade matte is now being shipped. The smelter contains 2 forty-ton furnaces, and is equipped with the latest type of roasters. The concentrator handles 250 tons of ore per day; \$1,600,000 has been expended, and there is said to be \$2,000,000 of ore on the dump. There are 12 shafts on the property, three of which are on the Big Copper vein, which has been traced for a distance of 3,000 ft. The Ore Knob mine in Ashe County, which has been abandoned for a number of years, resumed operations late in 1901, and the company owning the property is said to be erecting water-jacketed furnaces of the Garretson type to smelt its low-grade ore. This mine was worked by a Baltimore company when copper was selling for 8 to 9c. per lb., and \$210,000 of dividends were paid as a result of its operation. The ore runs about 5% copper. The copper mines of the Virgilina district have been mentioned elsewhere in this volume under the caption "Virginia."

**Tennessee.**—In the Ducktown district, according to reliable reports, the Tennessee Copper Co. has spent nearly \$3,000,000 on its plant and properties, and the Ducktown Sulphur, Copper & Iron Co., \$1,000,000. These two companies employ nearly 3,000 men. The last named company treats from 280 to 300 tons of roasted ore daily, producing about 3,000,000 lb. of copper per year, and distributed dividends amounting to \$140,000 for 1900 and 1901. Its cost of producing copper has been estimated at 10c. per lb. The Tennessee Co., owning 13,157 acres, began work in July, 1899, and 18 months later had 800,000 tons of ore blocked out. Its plant is very complete. The shaft houses contain crushers, rotary screens, Robins picking belts and 500-ton ore-bins, besides power and air compressor plants; 7.5 miles of standard gauge railway have been laid connecting the shafts, roast yards and smelter with the Atlanta, Knoxville & Northern R. R. The ore is roasted under sheds with a capacity of 83,000 tons. The smelter contains two water-jacketed blast furnaces 56×180 in. at tuyeres, and 18 ft. from tuyeres to charging floor, two converter stands, with six shells 7 ft. in diameter and 10.5 ft. long, which are handled by a 40-ton electric crane with a 50-ft. span. There are the usual accessories of electric slag cars, clay mills, etc. The power house has four 250-H.P. boilers, supplying two Nordberg engines. The estimated cost of production of copper by this company is 9c. per lb.

**Utah.**—The total production of copper for 1901 was 20,116,979 lb., against 18,504,726 for 1900, an increase of 1,612,253 lb. The Daly-West Mining Co. produced during the year 1,326,448 lb. copper from 31,344 tons of lead-silver ores and concentrates. The Horn Silver Mining Co. during 1901 produced 577,578 lb. copper from 1,410 tons of ore containing gold, silver, and lead. The Utah Consolidated Gold Mines, Ltd., which owns the Highland Boy mine, produced 9,043,967 lb. copper from its own ores, and during the year Bessemerized the matte smelted by the Bingham Copper and Gold Mining Co., producing therefrom an additional 1,041,801 lb. copper. The Bingham Co. is building its own converting plant, which will be in operation early in 1902. The Quincy Mining Co. in 1901 produced 984,169 lb. copper from 39,209,925 lb. of dry ore containing 9,826,007 lb. lead, 1,650,738 oz. silver, and 1,568.4 oz. gold. From January 1 until April 1,

1902, when the mine was sold to the Daly-West Mining Co., the Quincy Mining Co. produced from 16,023,819 lb. dry ore, 333,295 lb. copper, 4,021,979 lb. lead, 546,172 oz. silver, and 616·92 oz. gold. During 1901 considerable additions were made to the Salt Lake smelters. The American Smelting & Refining Co.'s Mingo and Hanauer plants were dismantled, and the Germania will probably be shut down when the new 1,000-ton plant is completed, probably in July, 1902. The new plant of the United States Mining Co., which owns the Centennial-Eureka mines at Tintic, is expected to be completed by September, 1902. This plant will consist of pyritic blast furnaces and converters and will have a capacity of 850 tons per day. The capacity of the Bingham smelter is about 400 tons of ore per day, and that of the Highland Boy about 500 tons of ore per day. The detailed statement from the reports of Utah copper mining companies will be found elsewhere in this volume under the caption "Gold and Silver Mining in the United States."

*Vermont.*—The Copperfield mines, at Copperfield, Vt., owned by Mr. George Westinghouse during 1901, pumped out the mine, straightened and widened the shaft so as to permit an output of at least 300 tons of ore per day, and began the erection of a smelter, which was not finished and in operation during the year owing to the difficulty in getting deliveries of material. The copper furnaces are two, of about 150-ton capacity each, and were erected by the Colorado Iron Works, of Denver, Colo.

*Virginia.*—(By W. H. Weed.)—The Virgilina copper belt is situated on the State line between Virginia and North Carolina, on one of the lines of the Southern R. R., 160 miles west of Norfolk. Although known for 40 years or more, the lack of railway facilities and the general disinclination of capitalists to invest in Southern mining properties retarded development until a few years ago. The investment of over \$1,000,000 in the field in the past two years, together with the active opening up of its veins, erection of mining and milling plants, and the employment of several hundred people, has brought the region into prominence. Active development has been confined to a radius of 8 miles from Virgilina, in which area there are now 14 mines being operated, four of which are steady producers; 17,000 tons is given as a rough estimate of the ore shipped during 1901, but this is scarcely a fair estimate as the ore must be concentrated before shipment, and the only mill so far erected was not started until last fall. The ores so far mined average about 3% copper, but shoots of high-grade ores (5 to 25%) occur in all the veins so far opened. The ores consist of copper glance and occasional bornite in a white quartz vein matter with admixed talcose altered country rock. The gold and silver values vary but slightly in the different veins, the gold averaging less than \$1 per ton, and the silver 6 to 10 oz. per ton in the ores shipped. The High Hill concentrator, working on an ore carrying 5·9% copper, 2 oz. silver, and 0·04 oz. gold per ton, effects a concentration of 11 tons into one, the concentrates carrying 40 to 50% copper, 0·24 oz. gold, and 20·3 oz. silver per ton. The shipping ore carries 4 to 5% iron and 68 to 75% silica. The ore is extremely siliceous and unfit for smelting without concentration. The high-grade ores are shipped directly to the New York works or to the Norfolk smelter. The deepest working of the Virgilina district is that of the

Holloway mine in North Carolina—510 ft. deep. The Person Co. has two shafts 150 ft. and 225 ft. deep, respectively. The High Hill (or Virginia Co.) in Virginia, two shafts of 231 ft. and 339 ft. depth. Numerous shafts from 50 to 150 ft. deep have been sunk on other properties. The favorable labor conditions, cheap fuel, proximity to tide-water, smelting plants, and railway communication all indicate that the ore can be mined, milled, and shipped profitably even at the price of copper prevailing early in 1902. The possible production of the field for the year 1901 to 1902 has been estimated by Caracristi at 4,500,000 lb. at a cost of 9c. per lb.

*Washington.*—Shipments of copper ore were made in the winter of 1901 by sleighs from the Republic camp to the Granby smelter at Grand Forks, British Columbia. The Kettle Valley Lines Railway connecting Grand Forks with the Republic camp will be completed early in 1902. The Tacoma smelter received the greater part of its ore supply from the islands and coast of British Columbia. The California mine on the line of the Kettle Valley Railway, made some shipments of ore to the Granby smelter. The values are principally gold, with some copper and silver, and it is reported that ore from the lower levels assays as high as \$239 per ton.

*Wyoming.*—(By Wilbur C. Knight.)—During the year upward of \$1,000,000 was spent in connection with the properties of the Sierra Madre Mountains. The Ferris-Haggerty mine remains as the greatest property yet discovered in that district. The Boston-Wyoming smelter, at Encampment, with a capacity of about 50 tons, was blown in last summer and worked until about the holidays. At first most of the ore was furnished from the New Rambler mine in the Medicine Bow Mountains, but later several properties about Encampment furnished ore, and especially the Ferris-Haggerty. On account of a long haul and bad mountain roads it was decided to construct a wire tramway about 16 miles in length, to be completed in July, 1902, at a cost of \$275,000. The tramway is to be divided into four sections and will be partly operated by steam power. The Ferris-Haggerty Co. has entered into an agreement to furnish this tram with 200 tons of ore per day at \$4 per ton for the haul. The discovery of various precious metals associated with the copper ore in the Rambler mine has been of very unusual interest. It is now definitely known that the ore contains platinum, iridium, osmium and palladium. These metals are not uniformly distributed through the ore and various samples assayed often show palladium, while others platinum alone. The majority of assays, however, show all four elements.<sup>1</sup> Prof. Wells has already shown that the platinum occurs in the form of sperrylite, and it is quite probable that the palladium also will be found as an arsenide belonging to the same mineralogical group. In the Laramie Mountains considerable prospecting has been followed. At Tie Siding, a Carboniferous or Permian grit has been opened that contains metallic copper and cuprite disseminated through the stratum. The metallic masses are of considerable size, those found on the surface weighing up to 100 lb. In the vicinity of Halleck cañon, about 50 miles N.E. of Laramie, are many promising copper prospects.

---

<sup>1</sup> See also, under the caption, "Platinum," elsewhere in this volume.

## COPPER MINING IN FOREIGN COUNTRIES.

*Argentina.*—Late in 1901 the CapiHitas Copper Co., Ltd., capitalized at \$3,000,000, was organized in London to operate the Capillitas and Atajo mines

THE WORLD'S PRODUCTION OF COPPER  
IN METRIC TONS

and the Pilciao and Constanica smelters in the Province of Catamarca. The smelters are about 30 miles from the mines and aggregate eight reverberatory

furnaces. It is stated that the Capillitas ores average 23% Cu, with some gold and silver.

*Australasia.*—The copper production of Australasia showed an increase of 7,875 tons in 1901, the total production of the metal amounting to 30,875 tons against 23,000 tons for 1900. The old Wallaroo & Moonta mines in South Australia materially increased their output, while considerable additions came from Mount Lyell, in Tasmania; Cobar, in New South Wales; and Queensland, which in 1900 shipped little of the metal, multiplied its output very considerably.

The copper produced in New South Wales during the year 1901 amounted to a total valuation of £413,302, against a total valuation of £428,036 for 1900, showing a decrease of £11,999. The number of men employed in the copper industry during the year 1901 is estimated at 2,964. The re-opening of the Kawau mine, on Kawau Island, in 1900, after its complete abandonment for 40 years, revealed an interesting deposit of native copper, formed by the action of the sea water on the sulpho-salts of copper and the subsequent decomposition of the copper chlorides by the iron present in the mine. Owing to litigation, the

(a) The figures in this table are taken from the annual metal circular of Henry R. Merton & Co., except where returns have been received by THE MINERAL INDUSTRY direct from official sources.

shaft on this mine was opened beyond the shore line, and after its abandonment the sea washed over and into the old workings and the chloridizing action of the sea water had full sway. The Cobar district of New South Wales presents many serious restraints to profitable copper working. The ores are so siliceous that direct smelting is impossible except at the Great Cobar mine. In concentrating, the losses are 50%, and when this loss is deducted from 3.5% Cu, the average copper content of the ore, and the scarcity of water, the heavy cost of shipping

the concentrates and smelting them elsewhere is taken into account, little profit remains. While the ores of the Great Cobar Copper Co. are of no higher grade than those of the rest of the district, the mixture of the gold-bearing ores from the oxidized surface zone, and the lower sulphide ores make an almost ideal smelting mixture. If the Cobar Chesny mine could profitably concentrate its siliceous ores, it has millions of tons in sight, but their concentration at present with 50% losses, makes profitable working out of the question. The slump in copper compelled the closing of all but the Great Cobar mines during the latter part of 1901, and this mine is working with reduced forces only for the purpose of completing contracts made some years ago for future deliveries to America. The Lloyd mine at Burranga is still working even with copper at its reduced price. This mine has now reached a depth of 1,750 ft., the width of the lode averages 5 ft., with a face of ore 700 ft. long on the line of the lode. The mine produced 21,000 tons of ore in 1901. A new plant was erected during the year at a cost of £32,000, and 500 men are employed. The new mining district near Bungendore, on the Goulburn-Cooma railway continues to look promising. The deepest shaft, 163 ft., follows a lode 25 ft. in width which assays 15% Cu. The Mount Fischer Proprietary Co. expects to erect a smelter on its property early in 1902. The lodes of this district run northward through slates and limestone, and appear to be true fissures.

There were 3,061 tons of copper produced in Queensland during 1901, against 384 tons of copper ore for 1900, a great increase of production due to the Mount Garnet, the Chillagoe Railway & Mines, Ltd., and the Einasleigh Freehold Copper Mines, Ltd. The Mount Garnet Freehold Copper & Silver Mining Co., Ltd., furnished an output of 1,462·3 tons of copper, and 311,586 oz. silver worth £163,000 from 37,179 tons of ore during the year. The smelters of the Chillagoe Railway & Mines, Ltd., after treating 8,129 tons of ore for a yield of 367 tons of copper, 15,721 oz. silver, and 75 oz. gold, of a total money value of £23,792, were closed down. The Einasleigh Freehold Copper Mines, Ltd., began to smelt its ores toward the close of the year, and treated 1,009 tons of ore for a yield of 104 tons of copper, and 1,330 oz. silver, of a total value of £6,600. Smelting operations were then suspended pending the completion of the tramway to the Chillagoe Railway. The Queensland Copper Co. acquired the Mount Perry and Ried's Creek Copper and Gold Mining Co. during the year and prosecuted active work on the Mount Perry mine, unwatering the old shafts, erecting a 60 to 80-ton water-jacketed smelting furnace, and connecting mine and works by a tramway. The production of the Normanby, Harpur's Hill, and Great Freehold mines in the Mount Perry district, was treated at the Aldershot works. The ores of Cloncurry were shipped to Wallaroo, South Australia, and as cost of transport is high, only the very rich ores could be shipped. The last consignment of 528 tons of ore forwarded in 1901 to the Wallaroo smelting works, by the Hampden Copper Mines, of Cloncurry, North Queensland, contained an average of 36·5% Cu, and after deducting smelting charges yielded £10,624, an average of £20 2s. per ton. They are reported to have stacked up at the mines 4,967 tons of second and third-class ores, containing gross values of £28,808. During the latter part of the year a new copper find was reported on the Malbion. Fifty

tons of ore lying on the surface were estimated to contain 40% copper. Reports from the Walsh and Zinaroo mineral field for 1901, estimate copper rock produced at 44,854 tons, with a yield of 2,369 tons of copper, valued at £150,978.

The Mount Lyell Mining & Railway Co. is still the most prominent copper company in Tasmania. In addition to the South Tharsis property, it purchased the Royal Tharsis in 1901. Reports for the fiscal year ending June 30, 1901, for the various mines show the following: Mount Lyell Mining & Railway Co. produced 9,243 tons of blister copper containing 9,132 tons fine copper; 619,734 oz. silver; and 22,911 oz. gold; the amount paid in dividends was £110,000, and a bonus of £13,750. The amount of ore treated at the reduction works for the quarter ending December 31, 1901, was 92,899 tons, from which 2,579 tons of copper, 160,102 oz. silver, and 5,002 oz. gold, the whole valued at £221,134, was produced. The number of men employed in mines and on railway was 1,993. The North Lyell mine shipped to Kelly's Basin 9,243 tons of ore, and to the Mount Lyell smelters 30,083 tons. This company is erecting a smelting plant at Crottyton, where a branch line connects the site selected with their permanent way. The Mount Lyell Blocks has completed the erection of the winding, electric, and compressing plant purchased from the Volunteer Gold Mining Co., at Lefroy. The mine produces about 70 tons of ore per day. The Lyell Tharsis mine produces about 60 tons of ore per day from open cutting and stoping. Systematic prospecting of the Birthday Copper Syndicate property on the coast about 20 miles south of Marquarie Heads, has revealed promising copper lodes, and extensive development of the property comprising 510 acres, will be made by the company.

*Austria-Hungary.*—The copper mines in Graslitz-Klingenthal, Bohemia, which were abandoned for 200 years, were re-opened in September, 1901. Considerable development work has been done, sinking straight shafts, making air connections with the old workings, and drifting and cross-cutting with the aid of machine drills. The ore lies in a formation of argillaceous slate from 12 to 15 ft. in width. The force of 80 men at present employed will be increased to from 1,500 to 1,600 when the smelting and ore-handling machinery is erected early in 1902. The production of copper for 1900 amounted to 141 metric tons for Bosnia, and 9,890 metric tons for Herzegovina.

*Bolivia.*—The copper formation of this country now being extensively developed at Corocoro, extends from Atacama, Chile, almost uninterruptedly through all the intermediary provinces to Corocoro, Bolivia, and thence northeast until it finally ends at Apolobama, in Peru, following the eastern chain of the Andes, as well as the spurs of that range. Early in 1901 the Bolivian Co., organized by Sir Martin Conway, obtained important mining concessions from the Government for a consideration of one-third of the annual net profits of the company, and in July, 1901, a scientific expedition equipped for an absence of a year was dispatched into the interior. This concession lies between the crest of the Andes and the great Amazonian plain, and between the rivers Kaka and Beni, and the river Pando or Tambopata, an area of over 10,000 square miles. During the fiscal year 1900-1901 the Government granted 1,172 permits for tin and copper mining, covering an area of 31,315 hectares, against 669 per-

mits covering an area of 15,295 hectares for the previous fiscal year. In 1900 Bolivia exported through Antofagasta, Chile, 178 metric tons of copper ores, and 38 metric tons of silver and copper ore, besides 87 metric tons of copper smalls and 0·868 metric tons of pig copper, the total value of the fine copper contents exported for the year being placed at \$451,000.

*Canada.*—(By W. M. Brewer.)—The production of copper in British Columbia for 1901 was 40,951,196 lb., against 18,919,820 lb. for 1900, an increase of 22,031,376 lb., due to the activity in Grand Forks and Kettle River mining divisions of the Boundary Creek district. The ores of this district are mined by quarrying on the surface or on the pillar and stope method underground, by which it is practicable to open stopes from 40 to 125 ft. wide, and of the same length, with air drills giving a service of from 50 to 100 tons of ore per shift. The costs of mining have been reduced to \$0·75 per ton, and at the British Columbia Copper Co.'s smelter the single furnace nominally rated at 300 tons of ore per day has averaged a burden of 367 tons for 11 months, and in December averaged 425 tons per day, reducing the smelting costs for the year to less than \$2 per ton. This smelter at Greenwood was blown in on February 18, 1901, and treated during the year 117,565 tons of ore. The Granby Consolidated Copper Co., which owns and operates the Knob Hill and Old Iron Sides mines, treated 230,928 tons of ore in 1901 against 62,387 tons in 1900, the highest daily average of the two furnaces in blast being 633 tons. This company has increased its smelting facilities to 1,300 tons of ore per day instead of 650 tons in 1900, and has also installed a Bessemerizing plant of two stands of converters to produce blister copper from the 50% copper matte formerly shipped. The Le Roi Mining Co., Ltd., in the Rossland district, reports for the fiscal year ending June 30, 1901, a production of ore shipped to the Northport smelter of 202,583 tons of ore averaging \$13·16 per ton in value. The working costs were: \$4·14 per ton, mining; \$0·51 for freight; \$4·83 smelting charges; \$1·23 for shipping and refining the matte; total, \$10·72 per ton. Average profit, \$2·44 per ton. The average content of the ore was 1·33% Cu, 0·35 oz. gold, and 0·6 oz. silver per ton. Owing to a strike at the Northport smelter, lasting from July to October, 1901, shipments were not made during that time. The Le Roi No. 2 mine shipped to the smelter during the year, 24,689 tons of ore valued at \$435,005 at a total cost for mining of \$277,624. The ore averaged \$9·18 per ton gold, \$0·92 silver, and \$7·55 copper. Costs per ton for stoping and loading on cars were \$2·90; development, \$0·125; machinery and plant, \$0·15; surface work, \$0·30; mine equipment, \$0·10; freight and treatment, \$6; reductions from gross metal values, \$1·98 per ton; total, \$11·56; leaving a net value per ton of \$6·09. The mine has a capacity of 250 tons of ore daily. The Hall Mining & Smelting Co., in Nelson district, B. C., was running during the year chiefly on custom ores, but in October, about 13,000 tons of ore from the Silver King mine owned by the company were treated for a yield of 6·5% copper and 37·78 oz. silver per ton. Of the mines in the Southeast Kootenay district the North Star mine paid in dividends during 1901, \$135,500, and the St. Eugene, at Moyie, \$210,000. Nearly all the ore bodies in British Columbia are lenticular, and like those of Vancouver Island, the gold-copper ores are sulphides. The Boundary district ores, to a great extent pyrrhotite, and some

chalcopyrite, average \$2 per ton in gold (though sometimes as high as \$15), about 2% Cu, and low silver values. Ores from the west coast of Vancouver Island are chalcopyrite, and vary from 4 to 16% Cu, about \$2 gold, and run low in silver; the east coast ores are chalcopyrite and pyrrhotite in a quartz and heavy spar (baryta) gangue, and average \$5 in gold, 6 to 8% Cu, and low silver values; the Texada ores, principally bornite, assay from \$4 to \$20 gold, about 5% Cu, and low in silver. Of the mines on Texada Island, the Marble Bay mineral claim shipped about 12,000 tons of ore during the year partly to the Van Anda smelter, and during the latter part of the year to Tacoma, Wash. The ores average from 0.24 oz. to 0.9 oz. gold, 5 oz. silver, and 7% Cu (dry assay). The Van Anda Copper & Gold Co.'s plant comprises a large wharf, warehouse, 125-ton smelter, sampling works, and assay office complete, and the company owns and operates the Copper Queen and Cornell mines; the ores average \$25 per ton in value. Other mines on the island shipped small amounts of ore to the Van Anda smelter during the year. On Vancouver Island, the Monitor Mining Co. shipped, during the year 996 short tons of ore, carrying 174,261 lb. Cu. The Tyee Copper Co., of Mt. Sicker made extensive development work and some ore shipments to the Tacoma, Wash., smelter during the year. This company will erect a smelter at Ladysmith early in 1902, of sufficient capacity to handle its own product as well as custom ore. A Montana syndicate also will erect a smelter during 1902, at Osborne Bay, a short distance from the Tyee smelter. The Three Jays Copper Co., on Alberni Canal, has made shipments to the Tacoma smelter during 1901, and having completed the aerial tramway, bunkers, etc., has chartered steamship capacity for monthly shipments of 3,000 tons to the Tacoma smelter, during 1902. The increase in production of Ontario for 1901 was 9,074,000 against 6,728,000 for 1900, the increase being due largely to the richer nickeliferous mattes shipped from the Sudbury district, although the non-nickeliferous mines on the north shore of Lake Huron also increased their output. The Westmoreland Copper Co., near Dorchester, New Brunswick, is reported to have expended over \$240,000 on mines and reduction plant, which includes dynamos, furnaces, crushers, and a series of 80 precipitating tanks. It is alleged that the mine has been developed to a depth of nearly 200 ft., and that the horizontal workings aggregate some 7,000 ft. in extent. The 150-ton plant of the Intercolonial Copper Co., at Dorchester, N. B., which was started in the latter part of the year, comprises crushers, roasting furnaces, and 50-ton leaching vats. The strong solutions from the sulphuric acid leaching are passed through an electrolytic precipitating process, while the wash waters are precipitated on scrap iron. The trial run was satisfactory. The mine has nearly a mile of underground workings, and the ores consist of chalcocite and copper carbonates in sandstone.

The Cape Breton Copper Co., at Coxheath, Nova Scotia, during 1901, continued development of its low-grade ore deposits, assaying 3% Cu, 0.09 oz. gold, and 4 oz. silver. Concentrating tests show concentrates assaying Cu, 9.9%; Fe, 27.3%; SiO<sub>2</sub>, 35%; while the tailings contain 1% Cu. The Colonial Copper Co., at Cape d'Or made extensive developments on zones in the trap rock, which carry metallic copper. About 70 men are employed in summer and 15 men in winter.

The company expects to become a producer in 1902. The Copper Crown Mining Co. did a small amount of work during the summer of 1901.

*Chile.*—(By W. E. Mathewson.)—The two large refineries at Guayacan and Lota produced their usual quota of Chile bars during 1901; the Guayacan refinery may have increased its output somewhat on account of the heavy shipments of matte from the Panulcillo furnaces which ran well throughout the year. The Guayacan and Lota plants produce the bulk of the bar copper exported from Chile, which is shipped by nearly every steamer of the Pacific Steam Navigation Co. leaving Valparaiso for Great Britain. There were several smaller plants in operation during the year, notably at Huasco, Chanaral, La Serena, Antofagasta, and Gatico. At the plant of the Fundicion Templeman, in Antofagasta, several hundred tons of argentiferous copper bars was produced assaying about 75 oz. silver per ton, all shipped to Great Britain, where this firm is interested in a refinery. At the Playa Blanca establishment of the American Smelting & Refining Co., near Antofagasta, 7,800 tons of argentiferous copper matte were produced, assaying 50% Cu and 390 oz. silver per ton, and shipped to their refinery at Perth Amboy, N. J. The low metal quotations at the close of the year together with the closing of the Playa Blanca plant seriously interfered with the mining of copper ores in the Province of Antofagasta. The bulk of the copper of that province is mined at Chuquicamata, a camp on the spur of the Antofagasta, Chile & Bolivia railway, about 267 km. from the port of Antofagasta. The mines are not yet very deep, 100 m. being the greatest depth attained. The surface ore is peculiar in that it is largely composed of the mineral atacamite, a volatile copper oxychloride. The output of the province was approximately 25,000 metric tons of an average assay of 13% copper. There were a few hundred tons of ore over 15% Cu shipped to Swansea, the balance being smelted locally.

EXPORTS OF COPPER FROM CHILE AND BOLIVIA.

NOTE.—The quintal is 101·5 lb. avoirdupois.

*China.*—In the French Province of Yunnan, lying between the Red river of the south, the meridian of Haiphong on the east, and the Blue river, are extensive copper deposits which have been worked by the Chinese for over 1,000 years, to such extent, that the forests have been entirely cut off to provide charcoal for the crude metallurgical processes, and the production of copper to-day is restricted by the lack of fuel. In the twelfth century the production of copper amounted to 6,000 tons, while to-day, it is not more than 1,500 tons. The accessible beds of copper are mostly exhausted, but modern methods and deep mining would probably yield rich returns. The Government has authorized the

construction of a railway from Lao-Kay to Yunnan-Sen, a distance of about 291 miles, and has ceded the operation of the 239 miles of railway already completed from Haiphong to Lao-Kay for 75 years, the contractor to assume the expenses of the whole, and share the profits with the Government. The working and building capital of the contractor amounts to \$19,493,000. Besides the copper mines, the completion of this railway will open up extensive deposits of mercury, tin, and coal.

*Cuba.*—There are a number of abandoned mines in Santa Clara province, some of which are near railway points. Among them are Mina San Juan de la Malaja, 6 miles N.E. of Santa Clara City, the district about Finca San Joaquin, about 30 miles N.E. of Cienfuegos; Mina Santa Rosa, 2.5 miles further east; prospects a few miles west of Cumanayagua; in the northern portion of the district of Trinidad; and there are three prospects near Sancti Spiritus.

Mina San Juan de la Malaja shows on surface a "blow out" 100 ft. across which is composed of yellow iron oxides, hematite, considerable quartz, and some copper carbonate. Sufficient depth has not been attained to determine whether or not there are sulphides beneath the gossan. The strike of the Mina Santa Rosa vein is N.45°W., and it dips steeply to the N.E. The footwall of the vein is composed of feldspathic rock, and the vein is 10 ft. wide, iron stained, and contains copper carbonate ores, iron pyrite, and chalcopyrite. The Finca San Joaquin district appears to be the only one which shipped to any extent. In 1856, 480 tons were shipped to Swansea, Wales, and 300 tons to the United States, the ores averaging 17% copper, with a total value of \$12,000. In 1868, 3,253 tons were shipped to Swansea, Wales, for which £54,446 was received; the average copper content was 19.7%. The mines were last worked from 1882 to 1885, and were then abandoned on account of the revolution. The Mina San Fernando vein is in diorite-porphry; the lodes are nearly vertical, and the gossan consists of iron oxide and quartz, with occasionally a good deal of blende. The copper ores are massive or decomposed azurites, red and black oxides, and purple and yellow sulphurets. At one point the lode measures 30 ft. in width. An analysis of a sample of sulphide ore yielded 8.36% Cu, 57.34% Fe, 0.15 oz. gold, 4.7 oz. silver per ton, and a trace of lead. The Mina San José vein consists of quartz in diorite porphyry, the ores are sulphides, and the mine waters contain a large percentage of copper.

*Dutch East Indies.*—The Pagoeat Co. is slowly developing a copper property comprising a vein of chalcopyrite and chalcocite ores which is 1.3 m. in width and carrying 10% Cu. The country is dioritic slate and the mineral is in a quartzose gangue. The Bone Co. claim to have an immense deposit of ore carrying 5% Cu. They propose to exploit the north coast of the island, which is called the "Gold coast of Celebes."

*Italy.*—The Etruscan Copper Estates at Campiglia, 2 miles from the railway station of San Vincenzo, made some explorations of its copper mines during 1901. These ancient mines have been variously reported on by different experts. It is doubtful if any extensive development of the copper mines will be attempted during 1902. The Etruscan Co. has however begun the erection of a reducing plant for their zinc-lead ores, which are found near their copper deposits. The

Libiola Copper Mining Co., Ltd., reports for the year ending December 31, 1901, a net profit of £6,095, from which £3,780 dividends were paid, leaving a balance of £2,315. A final dividend amounting to £2,520, payable in 1902, was recommended; 900 yd. of ground were opened up, and 5,229 tons of copper ore averaging 3.746% Cu, and 22,868 tons of pyrites averaging 47% S, were mined in 1901, against 5,700 tons of ore averaging 4.427% Cu and 26,211 tons of pyrites averaging 47% S, in 1900.

*Japan.*—For several years past the output of Japan has increased steadily by small margins and now exceeds 25,000 metric tons annually, being about on a parity with that of Chile. The number of producing properties is large, but more than 60% of the total product is contributed by the following mines, arranged in the order of their importance: Ashio mine, in Shimotsuke; Besshi mine, in Iyo; Ani and Arakawa mines, in Ugo; Osarusawa mine, in Rikuchu; Kusakura mines, in Echigo; and Ogoya mine, in Kaga. The Ashio mine which produces about 6,000 metric tons annually is located some 15 miles S.W. of Nikko, and is said to have been worked for a period of more than 300 years. The ore deposits consist of quartz and chalcopyrite veins inclosed between an eruptive rock of liparitic character and hard slate. It is said that the average content of the dressed ore is 15% Cu, while some of the richer material runs as high as 30%. The principal vein averages 12 ft. in width and has been followed in the workings for about two miles. As the deposits are located on the side of a mountain, they are opened by adits; recently, however, the construction of a shaft has been undertaken which will be used to exploit one of the smaller veins. The equipment of the mines is modern throughout and includes electric motors for haulage and electric hoists and pumps. Power is supplied from an hydraulic plant which contains four Pelton wheels and two turbines, developing altogether 450-H.P.

*Mexico.*—The plant and mines of the Rio Tinto Mexicana Co., a short distance from Chihuahua, formerly owned by an English syndicate which is reported to have spent over \$1,000,000 on the property without profitable recovery of the values in the ores, has been purchased from it at a cost of \$25,000 Mexican, reconstructed and improved at an expense of \$92,000 Mexican, and during the first 14 months of its operation earned the entire cost of plant and mine. As the slags under the English management ran upward of 2% Cu, some idea of the cause of former unprofitable working may be had. The mines of the Jimulco Co., situated about 75 miles south of La Descubridora mines, State of Coahuila, were reported to be in bonanza copper rock during the latter part of 1901. The Descubridora Mining & Smelting Co., in the State of Durango will complete the erection of its new electrical machinery for mines and smelter early in 1902. A company controlled by Pittsburg interests is erecting a 50-ton smelter near Eloro, Durango, which will use hot air in smelting for copper matte carrying gold. El Progreso Copper Mining Co. has been operating the mines in Jalisco during the year and considerable development work has been reported. The Santa Emilia Copper Co. constructed a 50-ton concentrating plant at its mines near Coapa, State of Michoacan, and the product is shipped to the Monterey smelters. La Mina de California Co., of the Guaymas district, State of Sonora, was organ-

ized during the year, with a capital stock of \$1,000,000 to operate 20 pertinacias of copper property, situated 3 miles north of the Yaqui river and 3 miles from the town of Cumuripa. The assays are said to average \$93 per ton in value, and the company is reported to be erecting a smelter.

The fuel gas plant of the Moctezuma Copper Co., at Nacosari, consists of two sets of two fire-brick lined generators, each 9 ft. 6 in. diameter by 15 ft. high, with a waste heat, vertical, multitubular boiler, scrubber, and Root's exhauster. By altering the exhaust speed the quantity of gas required for the varying power demands is secured. The producer and water gas are stored in separate gas holders and mixed later in fixed proportions. Each set of generators is in operation every other week, and develops 1,000-brake H.P. per hour in eight Crossly, four cycle gas engines rated at 110 H.P. at 200 revolutions per minute, which, in turn, operate eight 65 kw. 260-volt (shunt-wound, for protection against lapses in the gas engines), direct-current, General Electric generators, with a normal speed of 910 revolutions per minute. The consumption of New Mexican bituminous coal (containing 20% ash) is 1.5 lb. per brake H.P. per hour; with wood (scrub oak, etc.), about 3 lb. for the same unit. All of the ore (averaging 76%  $\text{SiO}_2$ ) is concentrated in a mill built in two sections, side by side, which contain the following machinery: two Blake crushers, two sets roughing rolls, one set finishing rolls (in common use by the two mills), 12 revolving screens, 24 Hartz jigs, two sets of 54×8-in. rolls, 5 Huntington mills, 24 six-ft. vaners, with smooth belts, and four with corrugated belts, and 10 Bartlett tables. The saving effected is 90% of the gross contents of the ore. Of the coarse concentrates 40% go direct to the smelter, and 60% are briquetted with 5% of clay. The two elliptical Copper-Queen-type, wrought-iron smelting jackets, measure 42×130 in. cross-section. The smelting charge consists of coarse concentrates, converter and fowl slag, calc spar, and "green" and flue-dust briquettes. The matte and slag flow into a tilting well, from which the latter runs continuously to waste, while the former is poured by tilting the well and flows thence by gravity to the two stands of trough-shaped converters, measuring 6 ft. 8 in. diameter by 9 ft. length, each. The converter-lining is lean gold and silver-bearing quartz, which is consumed by the low-grade matte at the rate of 1 ton per ton of copper produced. The converter and stack fumes, are partially recovered from an 8-ft. horizontal steel flue, by a conveyor, and further, from an inclined brick flue 750 ft. long, which empties at the top of the hill into a 70-ft. brick chimney. The production of fine copper during 1901 was 8,614,161 pounds.

The Greene Consolidated Copper Co., of La Cananea, Sonora, produced during 1901, 13,854,170 lb. of fine copper. This company's first copper furnace was "blown in" in December, 1900, the second furnace early in 1901, the third and fourth in October and December, 1901, respectively, and Nos. 5 and 6 were "blown in" early in 1902. The production of copper matte for the first four months of 1902 was 11,758,072 lb.; with silver, 114,426 oz. Before the middle of 1902 the new converter plant with a capacity per month of 6,000,000 lb. of copper matte, from six stands of converters, is expected to be in operation. The following detailed cost table will show expenses of copper production during 1901: Cost of mining, \$0.91 per ton of ore; cost of smelting to matte, \$2.14 per ton; hauling

from mines to smelter, \$0.15; total, \$3.20 per ton of ore. As the copper content of the ore averages 159 lb. per ton, the cost per lb. copper produced is \$0.0201. The matte shipped contains 1,000 lb. copper per net ton, and the freight to New York is \$12 per ton or \$0.012 per lb. of copper contained; Bessemerizing costs \$5 per ton, or \$0.005 per lb. copper; selling commissions \$0.005 per lb.; refining \$0.0025 a pound, making a total cost of \$0.0446 per lb. of copper. The 250-ton copper smelting furnace of the Copete & Melczer Mining Co., of Ures, State of Sonora, was put into operation in May, 1901, and it is reported that later in the year the construction of a concentrating plant was begun.

*Newfoundland.*—The Cape Copper Co., Ltd., at Tilt Cove, according to its report for the fiscal year ending August 31, 1901, produced at a gross profit of £60,591 which netted £47,909. During the year the East mine produced 54,253 tons of ore, averaging 3.28% Cu. The new South lode produced 10,268 tons of ore, averaging 4.27% Cu by wet assay, and the West lode 3,593 tons. During the year 78,089 tons of ore were shipped from Tilt Cove. The output of the East mine was distributed as follows: 33,922 tons sent to New York and 40,376 tons to Swansea, Wales.

*Norway.*—The Sulitjelma Copper Works, near Bodö, the largest in Norway, employed nearly 800 men and produced in 1899 about 40,000 tons of copper ores and pyrites. The mine has been considerably developed during 1900 and a much larger output is anticipated. The Lyngen Copper Works east of Tromsø is now connected by an aerial tramway with the Kaafjord valley and during 1900 produced 17,500 tons of raw ore which was subsequently concentrated. The copper deposits at the mine were only discovered in 1897, and have not yet been fully developed. The Killingdal mines produced 17,700 tons of ore in 1900 against 21,194 tons in 1899; the Drogset mine, at Meldalen, produced 2,718 tons pyrites containing copper, and the Ytteröen mine 1,300 tons pyrites. In addition to the above the mines at Alten, in Finnmarken, the Bosmo pyrites mine, and the Rorö, near Trohthjem, employing 600 men, all contributed to the copper production of Norway. A 50-ton Elmore process concentrating mill is working in Norway on ores containing iron and copper pyrites, and carrying value in gold. The ore is delivered to three batteries of five stamps, with screens of 20-mesh, which deliver to three McDermott "sizers" or submerged screens of 30-mesh. The coarse material goes to a Wilfley table, and the fines from the screens are treated on 3 six-foot Frue vanners, the tailings of which pass through the oil-process plant, consisting of two units of three mixing cylinders each.

*Peru.*—An extension of the Central Railway now completed from the seaport of Callao to Aroya, is projected to Cerro de Pasco, a distance of about 75 miles, which would cost about \$3,000,000 because of the great difference in altitude (Callao at sea level and Cerro de Pasco at an elevation of 14,300 ft.; total distance by survey 214 miles). The proposed charge of \$12 per ton freight from Cerro de Pasco to Aroya, against \$34 to \$39 the present charge for transportation on the backs of llamas should net a handsome profit to the enterprise. In 1900 about 12,000 tons of copper ores carrying 30 to 35% copper, and 4,800 tons of copper matte were shipped for export from Cerro de Pasco, a tonnage which could be largely increased with railway facilities. The Cerro de Pasco district is about

ware, and the ore deposits are reported to be practically inexhaustible. The mines of the district, 480 are owned by a mining company in which is the largest stockholder. It is reported that this mining company has 10 smelting furnaces of the capacity of 1,000 tons of ore per 24 hours, and a large plant.

The syndicate capitalized at \$600,000 in Lima, Peru, has undertaken the construction of the Rumiallana tunnel, abandoned 20 years ago with but 900 ft. of the total of 9,000 ft. for the purpose of draining the mines of the Pasco district. This syndicate is said to have contracted with various companies as follows: 50% of all the ores removed from the cuts and drifts along the length of the tunnel are to be the perquisite of the syndicate, while the mine owners are to give to the syndicate 20% of their total ore mined in consideration of the drainage of their properties. Should the individual owners wish to lease their entire workings to the syndicate, the latter are to assume all expenses of operation and account to the individual owners for 40% of the total ore removed by such operation. The Haggin Mining Co., however, denies the validity of such tunnel concession so far as its mines are concerned. It is reported that a syndicate is being formed to operate the rich copper mines in the Yauli district, 120 miles from Callao, at 13,400 ft. above sea-level. These mines are near a station of the Trans-Andine Railway, begun some 25 years ago.

*Philippine Islands.*—Extensive copper deposits are reported on the Island of Mindanao, in the region inhabited by the Moros, who have crudely worked these deposits for years. The Chinese and Philippine miners pound the ore to crumbs on anvil-shaped pieces of metal, the smaller pieces are then run through rolls. These rolls are stone or iron, in some cases, and disc form in others, and are turned around by water-buffalo power. Large furnaces for intensely heating the rock to soften it for crushing are found, and several smelting furnaces are in operation, the most successful ones owned by Germans. One German concern gets a plentiful supply of excellent native miners for a few cents per day each. Both gold and silver as well as copper, are found in Mindanao.

*Russia.*—In the provinces of Semipalaetinsk, Okmolinsk, and Karkaralinsk, in Siberia, important deposits of copper are being worked. These copper ores contain but little gold and silver. Nearly 600 licenses have been issued by the Government for the operation of the coal and copper mines of these provinces. The Russian production of copper for the year 1899 was 7,323 metric tons (447,082 poods), against an importation for the same year of 11,957 metric tons (730,000 poods), while in 1900 the production is estimated at 8,128 metric tons.

*South Africa.*—The report of the Cape Copper Co. for the year ending April 30, 1901, for South Africa, and August 31, 1901, for London and Newfoundland, shows a credit balance of £444,629, which includes £195,734 from the previous year. Of this, £11,191 was paid for income tax and £258,750 for dividends; £10,000 to sinking fund, leaving £164,688 to be carried forward, out of which a final 8s. dividend is to be paid January 1, 1902. During the year at the Ookiep mine 19,174 dry tons of ore and 2,521 tons of slimes assaying 10% copper were treated. The Nabaheep mine furnished 17,272 long tons of ore of 6.41% copper.

wet assay. The entire output of the two mines was treated at the local smelting works. At the Spectakel mine 439 dry tons were raised and at the Narrap and Trial mines satisfactory progress has been made. The Johannesburg Consolidated Investment Corporation, capitalized at 3,000,000 marks, has leased through Goerz & Co. the copper mining rights to the 16,800 square miles of territory owned by the German Colonial Co. in German Southwest Africa. This territory is bounded on the north and south by the Swakop and Knisib rivers, respectively, on the west by the English territory of Walfish Bay, and on the east by the sixteenth degree of longitude east of Greenwich. The Colonial Co. is to receive a bonus of £30,000, and 2·25% of the gross annual revenue from the mines. The copper deposits in question are reported to be very extensive and of great value. The asbestos and graphite deposits in the same territory have been leased to another syndicate capitalized at 80,000 marks. The Consolidated African Copper Trust, capitalized at \$3,000,000, has been organized to work the large deposits of copper which are reported to have been discovered in Rhodesia. It is said that the De Beers Co. and the Consolidated Goldfields of South Africa are interested in the new concern.

*Spain.*—The new smelting plant of the Rio Tinto Co., Ltd., strictly American in design and furnaces, was put into operation in January, 1902. The plant consists of two water-jacketed furnaces, each 160×42 in. at the tuyeres, with fore-hearths, 12 ft. in diameter, and 4 ft. deep, for the separation of matte and slag; and two No. 8 Connellsville blowers. The six 7-ton Bessemer converters (in two stands of three each) are of the trough type, 80 in. diameter by 120 in. long. The charge to the shaft furnaces consists at present of low-grade precipitates (55% Cu), high-grade pyrite ores (55% Cu), and sufficient quartzose pyrite ore (2 to 8% Cu, and 30 to 90% SiO<sub>2</sub>, balance pyrite) to yield a slag of about 37% SiO<sub>2</sub>. Five hundred tons of material (excluding the Welsh coke) are treated daily. Complete separation of the matte is prevented by the high density of the ferrous-silicate slag, and from 0·5 to 0·65% Cu remains in the slag. Of the three grades of precipitates produced containing 93%, 85%, and 55% Cu, respectively, the first two grades are shipped to Cwmavon, and the last 55% with its 3 to 4% arsenic, graphite and silica, is smelted with the ores in the blast furnaces to produce 50% matte. The highly siliceous quartzose ores are used for converter lining. The converter bars containing small amounts of silver and gold beside the copper are shipped to Cwmavon, Wales, for refining. The efficiency of precipitation of the Rio Tinto Co.'s leaching process amounts to a consumption of but 1·2 lb. of iron for each pound of fine copper produced. The Rio Tinto Co., Ltd., during 1901, realized on sales of copper and other items, including balance carried forward from 1900, a total of £1,505,692. Of this sum the following amounts were set aside: For the redemption of the 4% bonds, £65,800; plant out of use and charged off, £78,454; coal exploration, £10,000; depreciation of securities, £8,500; credited to reserve fund, £40,000; credited to provident fund, £4,000; total, £206,754. Out of the balance, amounting to £1,279,250, interim dividends of 2s. 6d. on the preference shares, less income tax (total, £38,424), and 35s. on the ordinary shares, free of income tax (total, £568,750), were paid, and dividends of 2s. 6d. on the preference shares (total, £38,255),

and 37s. 6d. on the ordinary shares (total, £609,375) were recommended, leaving a balance of £24,445 to be carried forward to 1902 revenue account. The total quantity of ore extracted during 1901 was 1,928,776 tons with an average copper content of 2.627%. The pyrites ore invoiced to consumers in England, Germany, and the United States amounting to 641,935 tons, contained 14,248 tons of copper, which, with the 21,100 tons extracted at the mines, made a total output for the year of 35,348 tons of copper. It was estimated that the reserve heaps at the mines contained 136,457 tons of fine copper, while the stocks at the company's works at Cwmavon, consisting of refined copper, copper in process, in precipitates and in matte, amounted to 6,062 tons. The Tharsis Sulphur & Copper Co., Ltd., reports for 1901 a total extraction of mineral from its Tharsis, Lagunazo, and Calañas mines of 732,389 tons against 770,995 tons in 1900, a decrease of 38,606 tons during the year. Calañas increased its production during the year by 29,970 tons, while Tharsis and Lagunazo fell off 68,576 tons owing to the almost complete exhaustion of the copper ores in these two mines. There still remains a quantity of ore carrying 49% of sulphur, but very small values in copper, from which the company hopes to derive some profit in future years. The exported ore amounted to 424,434 tons, while 307,955 tons were treated locally, from which the Metal works recovered 7,427 tons of fine copper as against 7,967 tons in 1900, a decrease of 540 tons due to lesser copper content of the ores as well as to smaller amount of ore treated. Total profits were £335,867, of which £42,081 was charged off to profit and loss account, £250,000 paid out as a 20% dividend, and £43,786 carried forward. Among other copper mines of Spain which are producers now or will shortly become so are the Escorial, Escorial Extended, La Recompensa, Huercal, and Coruna mines.

*Turkey.*—Rich copper mines, near Arghana Maden, which are owned by the Government, produce annually about 1,500 metric tons of ore, which is shipped through Alexandria to Great Britain. The ores are so rich that they are easily concentrated to 80% matte in one smelting operation. The copper mines at Tokat, and those near Dede Agatch are of smaller extent, and the ores are refractory. The Espie Bay Mines Development Syndicate, Ltd., of England, is operating the copper mines near Tereboli. The long abandoned Maaden-Keni copper mines near Baibourt on the Trebizond road, were re-opened under Greek management during 1901, and about 3,750 lb. of copper per month was extracted, amounting to a total production for 1901 of over 22 tons valued at £1,600, all of which was exported to Russia.

#### THE COPPER MARKETS IN 1901.

*New York.*—The course of the copper market during the year 1901 was followed with marked attention, not only by those directly or indirectly interested in the production and consumption of the metal, but also by the public at large. For the first time in years, the exigencies of the stock market had to be taken into consideration in trying to form opinions on the probable course of copper, although in the end, it is the inviolable law of supply and demand which governs the price of this as well as any other staple article.

Business in this country was very satisfactory, and the industries consuming

copper had their full share of activity. Both the wire and brass mills were very busy throughout the year, and while prices for the former product ruled comparatively low, those for the latter were well maintained, owing to the elimination of some sharp competition by the formation of the American Brass Co., which controls a large number of well equipped mills throughout the country. The railroads called for heavy quantities of the metal for use in the construction of locomotives and cars, and large orders were placed by shipbuilding firms for use in the construction of vessels for the Government and the merchant marine. The main increase in consumption, however, came from the electrical industry.

The consumption of sulphate of copper was satisfactory, and though the production is large, the stocks which were carried forward after rather a busy season, are not expected to last very long.

Exports during the year under review showed a marked decrease. In 1900 shipments to European ports amounted to two-thirds of the production; in 1901 to about one-third. The falling off in exports is due to the depressed condition of business in Europe, caused in England by the South-African war, and on the Continent by over-speculation. Naturally, new enterprises in which copper is required were suspended, and the result was a lessened demand on the part of the manufacturers. Aside from this, the disparity between foreign and domestic markets has led to a heavy increase in importations. The decrease in business in Europe was intensified by the reluctance on the part of manufacturers on this side to lay in stocks under present conditions. While thus consumers are practically bare of supplies, there is no doubt that the leading producing interests have been forced to carry the available stocks, which at the end of the year were variously estimated at from 150,000,000 to 250,000,000 lb.

The Amalgamated Copper Co., whose policy influences the market to a great extent, raised its capital from \$80,000,000 to \$155,000,000, for the purpose of acquiring the outstanding capital stock of the Boston & Montana Mining Co. and the Butte & Boston Co. It now controls about one-fifth of the world's production of copper. Negotiations were at one time under way with the object of having the principal producers join in a movement to restrict production. It is questionable if in the long run the disadvantages resulting from such a measure would not outweigh the advantages.

The year opened with Lake copper selling at 16·75@17c.; electrolytic copper at 16·25@16·375c.; casting copper at 16c. Business was rather dull, but improved during February, and a large demand sprang up for quick shipment. While Lake copper remained practically unchanged at 17c., electrolytic copper advanced to 16·5c. by the end of April. Consumption in this country during the summer months was very heavy, and aided by a fair demand from Europe values were easily maintained. It was not until the end of July that prices commenced to sag, mainly owing to the fact that consumers restricted their purchases to early deliveries. The ruling quotations in September were 16·5c. for Lake, 16·25c. for electrolytic, and 15·75c. for casting copper. In the meantime, the speculative market in London showed signs of weakness and the reports regarding the state of business in Europe were of a most discouraging nature. Exports of refined copper fell off to an alarming extent, while imports continued to increase, and rumors

were put into circulation, according to which the leading producing interests were carrying extraordinarily large stocks. The market recovered from the consequent depression and values kept fairly steady throughout October and November, but it soon became apparent that the Amalgamated Copper Co., which for such a long time had upheld quotations by asking 17c. for Lake and 16·25c. for electrolytic copper, would by force of circumstances be obliged to meet the market. Europe did not send any orders whatsoever; exports were alarmingly small; copper shares on all the exchanges were depressed and stocks continued to accumulate. A sale of a round quantity on private terms, carrying with it as it seems a guarantee of price, was reported at the end of November only to be followed by an open cut of about 1·25c., thus reducing the quotations to 15·375c. for Lake and 15c. for electrolytic copper. This was followed by a cut to 14c. for Lake, 13·875c. for electrolytic, and 13c. for casting copper, and another, one to 13c. for Lake copper, 12·875c. for electrolytic, and 12·5c. for casting copper. These prices were freely met by the outsiders, but, naturally, the market was utterly demoralized and business practically at a standstill, consumers preferring to await further developments. The quotations at the end of the year were 12@12·5c. for Lake, 11·75@12c. for electrolytic, and 11·5@12c. for casting copper.

*London.*—January opened with a visible supply of 28,860 tons, compared with 22,817 tons at the commencement of 1900, and with standard copper at about £73 spot and £73 12s. 6d. three months. Owing to the increase of the Bank of England rate of discount to 5% and to the apparent indifference of the American manipulators, values soon became easy and touched £70 12s. 6d. and £71 5s. for the above-named prompts. Consumption during this period was good, but purchases were made only for immediate needs. February commenced with the visible supply at only 152 tons above the previous month's, but prices eased off a shade owing to realizations and a want of speculative interest. On the resumption of buying by parties identified with the Amalgamated Co. there was a slight improvement to £71 15s. cash and £72 7s. 6d. three months, but some "bear" selling soon pushed the prices back about 10s. per ton. There was rather better demand from consumers, and the English Government also bought fair lines for stock. March started with the visible supply at 28,995 tons, against 28,904 tons at

the end of January, and after £71 5s. was done for cash and £71 15s. for three months, dullness again became apparent, and prices were allowed to drift to £67 10s. cash and £68 three months. There was no sign of reaction until the middle of the month, when the statistics showed a substantial decrease and this caused a rally to £69 10s. and £70. Consumers bought freely at the decline, more particularly on the Continent. April witnessed a better speculative feeling, induced by the strength of the share market in America and the intervention of American supporters in the metal market. Prices steadily rose until cash touched £71 and three months £71 10s., but just at the end of the month there was a sudden break to £69 10s. and £70, respectively. Trade with manufacturers was good and they bought freely in all kinds of copper. The War Office and Admiralty also purchased largely, with the result that at the beginning of May there was a better tone prevailing and the market improved to £70 10s. for early delivery and £71 for forward. At this time the Amalgamated Co. and other large producers were offering Lake and electrolytic copper at reduced prices, and most of the chief consumers were speedily filled up. The American railway share market also had a shake up at this time, causing a reaction in the standard market, prices declining to £69 spot and £69 10s. for later deliveries. June statistics gave 27,231 tons as the visible supply, but the standard market entered into a period of inactivity and business became a matter of mere jobbing between insiders; values consequently underwent but very little change, the whole of the fluctuations being covered by 20s. per ton. Trade with consumers was quiet, the chief demand being for copper suitable for electrical and ammunition work. Tough was also scarce owing to the firm attitude adopted by the principal producers. July opened with a dull outlook, the figures giving a slight increase in the world's supply of copper. Standard, after commencing at £68 cash, fell away to £67, three months' metal offering at 10s. advance. American operators gave some support at this level and caused an improvement of about 30s. per ton, but this was partially lost before the end of the month, when the closing rates were £67 10s. cash and £67 17s. 6d. forward. Trade remained quiet and consumers were only buying on a limited scale.

August began with the stock at 27,395 tons, but the metal trade was greatly disturbed by the strike in America among the iron workers and many people took fright and sold copper freely, causing a rapid decline to £65 5s. cash and £65 12s. 6d. forward. This level was touched about the middle of the month and reports then spread of further arrangements with the Amalgamated and other large producers: in fact, it was suggested that a giant copper trust was to be formed which would embrace all the largest producers of the world. The rumor was good enough to give speculation a fillip and values speedily recovered to about £67 10s. cash and £67 15s. three months. One of the largest of the European outside producers gave an absolute denial to the report and profit taking soon ensued, causing a setback to £66 10s. and £67. The advance in standard gave users of copper more courage and they bought rather freely. It was also stated that some of the larger mines in America were shut down for a time. September opened with a substantial shrinkage in the visible supply, which stood at 25,821 tons, being a reduction of over 1,500 tons on the month. These figures were

responsible for a rise to £67 10s. cash and £68 three months, but the receipt of the news of the dastardly attempt on the late American President's life was a disturbing factor, and this market, in sympathy with all others, experienced a relapse. Reports then arrived from America predicting an early reduction in price by the Amalgamated Co., and this naturally caused uneasiness among speculators and a want of confidence with consumers. The stock markets in America and in Paris and London quickly gave way to a state bordering on panic, the result being that standard quickly descended to £60 10s. cash. The Amalgamated then publicly announced that they were not going to cut their price, and there was a sharp recovery to £63 5s. cash, £63 12s. 6d. three months, at which the market closed. Demand for consumption up to the time of the publication of the above recorded unfavorable rumors was good, but naturally fell off very materially toward the end of the month. October figures showed a further shrinkage in stocks which stood at 24,765 tons, and values of standard continued to improve until £65 was touched for cash. Renewed selling, based on share movements, then caused a decline to £63, but smelters bought good lines of standard to convert into refined, and an improvement was again made to the region of £65 10s. The dealings were on a large scale and fluctuations were violent. Prices dipped again as low as £62 5s. cash, and £61 5s. three months, only to be followed by an advance to £65 and £64, respectively. November commenced with a large decrease of nearly 4,000 tons in the visible supply and values were strong in the neighborhood of £66 cash and £65 forward, and remained so until just at the close of the month, when a decided raid on forward metal was commenced by one firm who threw large lines of forward metal on the market, much to the bewilderment of the whole of the operators. Sales were so persistent and of such magnitude that we witnessed a time more exciting than has been seen since the break up of the French syndicate. December proved to be the most exciting month of the whole year, commencing with renewed aggressive selling on behalf of a prominent dealer, who in the best informed circles was supposed to be selling on behalf of the Amalgamated crowd, and this hammering continued practically throughout the month with only a few days' intermission, but immediately values showed any signs of steadying a further onslaught was noticeable. Reports from America as to continued reduction in the United Metals Selling Co.'s price also helped to aggravate the weakness of the standard market, and just before Christmas affairs took a still more sensational turn, owing to the suicide of a well-known broker. This was followed by the failure of one of the oldest firms on the London Exchange, which was due to the weight of metal that they were carrying. As their commitments in this article were heavy, there was another setback in values, which on December 20 declined to £48, but later in the day reacted to the neighborhood of £49. The year closed with standard copper selling at £49 2s. 6d. for spot, £49 2s. 6d. for three months also.

## PROGRESS IN THE METALLURGY OF COPPER DURING 1901.

THE following notes on the progress in the metallurgy of copper during 1901 have been abstracted chiefly from the technical literature of the year in addition to information and criticism which have been obtained by direct correspondence or discussion with practical metallurgists.

*Automatic Sampling.*—(By Paul Johnson.)—In THE MINERAL INDUSTRY, Vol. IX., is a short description of the automatic sample mill of the British Columbia Copper Co., at Greenwood, B. C. In order to utilize the gravity principle these samplers were designed to avoid elevating the material before it was crushed, and sample cut twice, thus necessitating the lift of 2% of the total ore sampled only, which is crushed to a size below 1.5 in. and is not hard on elevator belts and buckets. The endeavor was made to use construction drawings of the ordinary mechanical samplers, but these took more vertical room than could be spared. The height available was but 36 ft. and it was desired to reject the material direct into the gravity bins after crushing and sampling without further mechanical elevation.

Since erection over 100,000 tons of various ores have been sampled and check-sampled, and actual practice has proved the correctness of the system. The practice at Greenwood is as follows:—

The ore for sampling at the smelter is brought to the upper ore bins, which are six in number, in two parallel rows, side by side, each bin being 50 ft. long; the railroad tracks are over the center lines of these bins. The greater bulk of the ore is delivered to the smelter in dump cars of from 30 to 35 tons capacity, which are unloaded into the bin below by opening two bottom doors. When the ore comes in box cars it must be unloaded by shoveling into the side bin adjoining the one over which the car stands. The ore is withdrawn from the bin through ore gates 3 ft. wide by 2 ft. high into ore scoop cars on rails, which hold from 1 to 1.25 tons of ore and are brought down on a tramway of 1% grade to the top floor of the sample mill. One man can handle two cars, as, when started, they go by themselves. The cars are first weighed on a Fairbanks scale to check the railroad weight scale and then dumped into the large hopper of a No. 5 Gates crusher. Pieces over 11 in. thick are reduced with 16 lb. sledge hammers to enable them to pass the 11 in. opening between the corrugated crusher-head and the concaves of the crusher. The crusher is set to crush to a size of from 3 to 5 in. and corrugated crusher-heads are used. If the pieces do not exceed 10 or 11 in. in size this crusher will easily crush one ton in from 30 to 45 seconds. The crushed material is spouted down to the first Johnson No. 1 sampler, which makes between 6 and 7 revolutions per minute, and cuts out either 10 or 20% for first sample, as desired, and is made large enough to permit the passage of 10 to 11 in. pieces, largest dimension, without catching in the sampler. The rejected 80 or 90% falls through the spout into ore bin No. 1, whereas the sample goes through the sample spout down to a No. 2 Gates crusher. The sample is then crushed in the second crusher to a size of from 0.75 to 0.25 in., and passes through a No. 2 Johnson sampler. This cuts out three samples for each revolution, and makes 9 revolutions per minute; 20% is taken for sample, and

the remaining 80% is rejected to ore bin No. 2. The sample is spouted down to the boot of the elevator and lifted about 55 ft. above the top floor of the sample mill and dumped through a chute spout down to a No. 0 Gates crusher, which crushes the pieces to from 0.25 to 0.5 in. in size. The material is then spouted to a No. 3 Johnson sampler, which makes 12 revolutions per minute and cuts three samples for each revolution, removing 20% for sample. The 80% part is discharged into ore bin No. 1, and the 20% part for sample drops on a sloping feed table which, with a jerking motion, feeds the sample into a pair of 10×16 in. Reliance rolls, which are intended to crush the sample to an average fineness of 0.125 in.; it then passes through a fourth Johnson sampler of the same size as the previous one. The 80% part is again rejected, being dropped directly into ore bin No. 1, and the remaining 20% part is conducted down through a spout and an 8-in. pipe to the sample buggy car holding the final sample, which, when finished, is taken to the quartering plates, and cut down and mixed from 1 to 3 times, according to the size of the sample desired. The sample is then taken to the sample grinder, ground, again mixed and quartered down on the bucking plates, and then ground to pass a 100-mesh sieve. From this pulp, the final sample is taken, generally three bags, filled and sealed; one for the smelter, one for the ore shipper, and the third for umpiring.

By these proceedings the total quantity of the ore received is crushed and submitted to the sampling, and if 10% is taken for the sample after the first crushing, and afterward a 20% part, each time, it will thus be seen that the final sample in the sample car will weigh  $0.1 \times 0.2 \times 0.2 \times 0.2$  or equal to 0.0008 ( $\frac{1}{1250}$ ) part of the entire lot. If a lot is not large only  $0.2 \times 0.2 \times 0.2$ , or 0.008 ( $\frac{1}{125}$ ) part of the lot is taken for final sample.

Below are given results of assaying check samples of various lots; two independent samples, *a* and *b*, being taken of each lot, which shows how nearly equal two independent samples may be obtained by this system of sampling.

| No. of Lot. | Sample | Weight. | Copper. Wet Ass'y | Gold. | Silver. | No. of Lot. | Sample | Weight. | Copper. Wet Ass'y | Gold. | Silver. |

*Smelting Copper Ores at Greenwood, B. C.*—(By Paul Johnson.)—The plant, of which a description was given in THE MINERAL INDUSTRY, Vol. IX., commenced operations on February 18, 1901, with one blast furnace, 42×150 in. at tuyeres, which has been kept continuously in blast, except for nine days for repairs in August. Between February 18 and December 31, 1901, 117,077 tons of ore were smelted in this one furnace, which produced 3,714 tons of matte, assaying from 45 to 60% Cu, from 2 to 6 oz. in gold, and from 10 to 30 oz. in silver per ton. Besides Mother Lode and Boundary ores, some gold quartz ores of 80 to 90% SiO<sub>2</sub> have been smelted, fluxing with the Mother Lode ores. The largest tonnage was put through during December, when 13,098 tons of ore were smelted, averaging daily for the entire month 422·5 tons of ore. The largest tonnage smelted in one day was on January 10, 1902, when 459 tons of ore were put through the furnace. To handle this amount of material and to break up and pile the matte produced, the blast furnace department proper, in 24 hours employed 29 men, viz., 6 charge wheelers, 4 coke wheelers, 9 feeders (on 8 hours' shift), 2 charge weighers, 2 furnace men, 2 matte-tappers, 2 roustabouts, 2 foremen; thus, during December 14·5 tons of ore per man and shift were handled. Counting the total force of the smelter, the sample mill requires 10 men for unloading and crushing ore, sampling and distributing same into ore mixtures, and loading the shipping matte. Engineers, foremen, 1 blacksmith with a helper, and 1 carpenter, add 8 more men to the force, making the total number of men employed, including foremen, 47 men, which at 422·5 tons of ore put through daily, makes 9 tons of ore handled and smelted for every man employed.

The complete assay of three large lots of the iron, lime and sulphur ores smelted is given in the subjoined table:—

The character of these ores is not only self-fluxing, but at times rather basic, and sometimes as much as 5 to 6% of quartz ores have been smelted to advantage with them.

Before starting up the furnace it was somewhat doubtful whether or not a higher grade matte than 30 to 35% Cu could be made without resorting to roasting the ore, but actual practice demonstrated that the iron ore, which contains magnetic Fe<sub>3</sub>O<sub>4</sub>, in smelting, and reducing its iron to Fe<sub>2</sub>O<sub>3</sub> for the slag, gives off one atom of oxygen for every molecule of Fe<sub>3</sub>O<sub>4</sub>, and this oxygen acts as such a powerful desulphurizer that in fact as much as 85 to 90% of the sulphur on the charge has been burned off at times. A 45 to 50% Cu matte was desired, but sometimes it has attained over 60% Cu, with an excess of the iron ore on the charge. It is an interesting fact in connection with making this high-grade copper matte, that whenever the matte begins to come up to 53% Cu and above, the gold will

"lock up" in the furnace in metallic copper bottoms formed. In one week making 58 to 63% Cu matte gold to the value of \$6,000 was locked up in the furnace bottom. The following week, using sulphur ores to bring the matte down to 45% Cu all of the "locked up" gold was regained in five days. Silver, however, does not behave in this way.

The Mother Lode ore is exceptionally free from arsenic and antimony, and behaves quite differently in the furnace as compared with the Silver King ore, which I formerly treated at the Hall Mines Smelter, Nelson, B. C., and which ore then carried quite an amount of arsenic and antimony, a purple-red colored smoke emanating from the chimney. When running the Silver King ore metallic copper and speiss separated out as soon as the matte came up to 47% Cu, which raised the furnace and settler bottoms and caused very great trouble by filling up the tap hole, thus menacing the plugging up of the furnace. In Nelson, on this account, the trapped spout was changed to the ordinary way of stopping up the tap hole with clay, and when the furnace bottom was "raising up" inside the tap jacket the furnace was blown through the tap hole for five minutes, the heat produced melting away the metallic obstructions. Using trapped blast with the Mother Lode ore as high as 67% Cu matte in the blast furnace has been made without filling the tap hole with metallic copper.

For its size (42×150 in. at the tuyeres) the furnace has a very unusual record for large tonnage and at the same time clean slags. The coarseness of the ore has more to do with tonnage and to some extent clean slags than anything else under similar circumstances. This was found out when we crushed the ore to 5-in. size, having gotten a wrong crusher head before, which crushed the ore to 2 and 3 in. A few percentages of silica, more or less, in the slag does not "slow up" these big furnaces as quickly as it does small furnaces, nor is an excess of lime as bad. If the iron in the slag comes up to 30 or 32% and silica at the same time is low, say 28 to 30%, a heavy slag is made and a correspondingly poor separation of the matte ensues, which is very troublesome and increases the copper in the slag. Examples of some different kinds of slags made, with the corresponding tonnage and tenor of copper in the slag are as follows:—

April 1, 1901, the slag assayed  $\text{SiO}_2$  33·8%, FeO 25·4%, CaO 25·7%, and Cu 0·25%; matte 49% Cu, the tonnage 402 of ore; high lime has a tendency to make the slags clean in Cu.

July 7, 1901, the slag assayed  $\text{SiO}_2$  30·9%, FeO 32·5%, CaO 16·8%, Cu 0·44%; the matte 53% Cu, the tonnage 399.

November 7, 1901, the slag assayed  $\text{SiO}_2$  42·7%, FeO 21·1%, CaO 20·0%, and Cu 0·33%; the matte assayed 44% Cu, and furnace smelted 393 tons of ore.

January 10, 1902, when the furnace put through 459 tons of ore, the slag assayed  $\text{SiO}_2$  37·8%, FeO 24·5%, CaO 20·9%, and Cu 0·35%; the matte assayed 49% Cu.

The concentration has varied from 15 to 70, but when the matte fall is below 2% the furnace does not work well, there is too little heat brought down in the crucible; this is especially pronounced with a rather siliceous slag, which causes the light to go out of the tuyeres and raises the smelting zone.

Slag samples for copper are taken twice daily, but are not assayed by the generally adopted colorimetric method, which as a rule gives too low results. The slag samples are taken every hour, chilled in water, the day and night shift slags being kept apart. Two grams are taken for the determination, dissolved in aqua regia, evaporated with  $\text{H}_2\text{SO}_4$ , diluted and copper precipitated with hyposulphite of sodium solution, the  $\text{Cu}_2\text{S}$  dissolved in  $\text{HNO}_3$ , and titrated with  $\text{KCy}$ ; this determination takes somewhat over two hours, carrying other work along with it, but it is correct and reliable, and it will check to 0.01% Cu, and where there is very little copper on the charge it is important to have accurate determinations of the slags and to keep them low in copper, as 0.1% Cu makes quite an important item. These daily slags are then put together, and once a week the average of all the slags is made for gold, silver, and copper. The slags, as a rule, have been very clean, the copper varying between 0.3 and 0.037%; gold between 0.0025 and 0.0035 oz., and silver between 0.04 and 0.07 oz. per ton. Of course one is allowed more copper in the slag and still considered to do good work making a 50%-Cu matte, than in making a 30%-Cu matte. A former rule was that good smelting was accomplished when one had only 0.1% Cu in the slag for every 10% Cu in the matte. Thus, making a 30%-Cu matte allowed 0.3% Cu in the slag, etc.

The amount of coke used is from 11.5 to 12% of the weight of the ore. The blast used is from a No. 7.5 Connersville blower, making 155 revolutions per minute, and giving 80 cu. ft. of air per revolution. The blast pressure averages 1.75 in. mercury, equal to 14 oz. Feed height above tuyeres varies from 4 to 8 ft.; when little sulphur or much coarse ore, feeding high; when much sulphur or much fine ore, feeding low. The best feed height for good running was found to be from 7 to 8 ft.

In running the furnace 3-ton charges are put in at the feed floor by feeders, and not by mechanical devices which are costly in diminished tonnage, bad working of the furnace, and yield dirtier slags.

A charge comes down to the tuyeres in 45 minutes; slag and matte run together continuously through a trapped spout into a water-jacketed forehearth on wheels, inside dimensions being 8×5.5 ft.×3 ft. deep. The matte, having a sp. gr. of from 5 to 5.3, sinks to the bottom, and the slag of a sp. gr. of about 3.4 to 3.5, overflows at the furthest end into a large settling pot, and from this into the granulating flume. The matte is tapped at intervals into matte pots, and their contents poured into matte molds 2×5 ft.×4 in. deep, thus cooling off the matte quickly and delivering it into the shape of cakes from 1 to 1.5 in. thick; these matte cakes when cooled are knocked on the top side with sledge hammers and broken up into 3×5-in. pieces and shipped in bulk in box cars, the lots averaging 30 tons. This does away with a crusher and sacking and makes the matte pots last longer.

During the latter part of 1901 the capacity of the smelter was doubled by the construction of new sets of lower ore bins, twelve in number, with an increased storage capacity of 5,000 tons of ore, making a total storage capacity for the lower ore bins of 10,000 tons. Another railroad trestle 560 ft. long has been built between the two already constructed in order to handle over 1,000 tons

daily of material for the smelter by the railroad. The foundation for the furnace building extension and the new furnace are in, and cast iron columns and furnace deckplates are put up. The furnace will be finished as soon as the cold weather allows the building of the brickwork for it. The new No. 75 Connersville blower is ready and in place for the furnace. With this second furnace completed, the plant will have a daily capacity of over 800 tons of ore, and together with coke, coal and matte shipped, the railroad will have to handle nearly 1,000 tons daily. The operation eventually of three to four furnaces is contemplated, and it is intended to add a converter plant to run the matte to blister copper, thus saving the freight on the copper to New York and on the refining charges on the copper now in the matte.

*Copper Smelting Jackets.*—The use of drop furnace bottoms supported by screw jacks resting on and attached to a car, traveling on a track beneath the furnace, came into general use during 1901. Among the furnaces erected with this type of bottom, were the 42×160-in. jackets erected by the Allis-Chalmers Co., for the Rio Tinto Copper Co., Ltd., of Huelva, Spain, and three furnaces built by the Colorado Iron Works, two for Mr. George Westinghouse for erection at Copperfield, Vt., and one for an Arizona company. A patent was applied for on the carriage furnace bottom by a Denver, Colo., mining engineer during 1901. The Mountain Copper Co., at Keswick, Shasta County, Cal., during 1901, adopted the use of water jackets made entirely of copper instead of cast or boiler iron, as formerly. The cost of the copper jackets is said to be \$75, as compared with \$20 for cast jackets, and they are made in the company's foundry from metal obtained from the cement copper leached at the mine. It is said that the life of the copper jackets is so much greater than those made of cast iron, or the copper-lined jackets, that notwithstanding the greater first cost, considerable economy is effected by their use. The use of copper spouts instead of cast iron ones is also increasing.

*Blowing Engines for Copper Smelting.*—The United States Mining Co., at Murray, Utah, installed during 1901, three blowing engines, displacing 75,000 cu. ft. of free air per minute at 2.5 lb. pressure, for use in connection with its copper matting plant. The blowing engines are designed by Edwin Reynolds to be driven by cross compound condensing Reynolds-Corliss engines. A comment on the use of blowing engines in preference to rotary blowers is made by Hiram W. Hixon,<sup>1</sup> who states that, irrespective of the work to be done, the blast pressure will depend entirely on the charge burden in any kind of blast furnace work, and that the charge burden governs the reducing action of the furnace altogether. Along these lines the iron industry has raised the charge burden up to 100 ft. to secure the full benefit of the reducing action of the carbon monoxide on the ore. Mr. Hixon further states that by using a blowing engine and consequently high blast pressure in a copper matting furnace run with the intention of producing as high a grade of matte as possible, by the oxidation and elimination of iron and sulphur, it would be impracticable to run a low charge burden in the furnace, and the proper conditions of oxidation of iron and sulphur cannot be obtained with a high charge burden. The reducing action in the furnace is

<sup>1</sup> *Engineering and Mining Journal*, 1901, p. 64.

effected almost entirely by the gases, and when these are permitted to go to waste, reduction ceases.

*Hot Blast Stove for Copper Smelting.*—An installation of the Bretherton hot blast stove (Fig. 1) has been made at the smelting works of the Val Verde Copper Co., at Val Verde, Ariz., in connection with a round 48-in. blast furnace. The air supply for the stove is drawn through air jackets situated above the water jackets of the smelting furnace, and the small amount of heat recovered in this way costs but little more than the extra expense of the jackets.

FIG. 1.—THE BRETHERTON HOT BLAST APPARATUS.

As installed by the Val Verde Copper Co., Val Verde, Ariz.

The heat evolved by the matte and slag in the forehearth is passed through the flues of the stove, and if this heat is not sufficient it is supplemented by an extra wood or coal fire. The temperature of blast claimed to be obtainable by means of this stove is 325°F., and the saving of coke by the use of the blast is said to be considerable.

*Details of Construction of Furnace Flue for Warming Blast.*—This apparatus as shown in Fig. 2 consists of a chamber arranged in the form of a hood over the entire top of the dust flue, for the purpose of abstracting the heat of the flue-dust and gases passing off from the furnace, and incidentally assisting the opera-

tions of the dust chamber by the contact of the hot gases against a cool surface, which tends to throw the dust out of mechanical suspension in the hot waste gases. Four pipes connect the hot air chamber with the bustle pipe of the four furnaces.

*Roasting Copper Matte.*—To facilitate the roasting of dense copper matte it is sometimes cast in sand beds made of flue-dust from copper furnaces which produces a spongy porous material of one-third the average density of similar matte cooled in iron molds. This porous condition of the material acts very satisfactorily in the subsequent treatment in the fusion furnace, especially when charged with siliceous fines that otherwise would be troublesome. Mr. F. Longford has obtained very good results by casting the matte in this manner. The flue-dust was dampened to pack it and allowed to dry in place so as to avoid the

FIG. 2.—DETAILS OF CONSTRUCTION OF FURNACE FLUE FOR WARMING THE BLAST.

danger of violent explosion. The porous condition of the matte is produced by the escape of gas which when set free caused bubbling and miniature explosion.

*Customs Decision on Copper Matte and Regulus.*—Early in 1902 in an appeal of the El Paso Smelting Works from the decision of the Collector of Customs at El Paso, Tex., to the Board of General Appraisers, it was held that copper matte containing lead is included within the term "copper, regulus of" in paragraph 534, Act of July, 1897, and as such is entitled to free entry. In the subject of this protest the lead contained in a certain quantity of copper matte was assessed for duty at the rate of 1.5c. per lb., under part 181 of the Act of July 24, 1897, which provides "Lead-bearing ore of all kinds, 1.5c. per lb. on the lead

contained therein." The assay of the copper matte in question was 47·64% Cu and 18·43% Pb. The full decision may be obtained by reference to the *Engineering and Mining Journal*, April 19, 1902.

*The Thermo-Chemistry of the Copper Bessemerizing Process.*—In an article on "Converters for Copper," by M. P. Jannettaz,<sup>2</sup> the thermo-chemistry of Bessemerizing copper matte is given much as follows: Mattes containing copper, iron and sulphur varying according to the nature of the mineral, as well as arsenic, antimony, bismuth, tin, lead, zinc, nickel, cobalt, silver and gold, deport themselves in the converter according to the principle of the maximum work performed, or those compounds are formed which give off the greatest heats of formation. The following table contains a series of columns contrasting the

THE HEAT OF FORMATION OF OXIDES AND SULPHIDES.

| Elements.    | Typical Formulas of Combination.           | Heats of Formation in Calories at 15° C. |                | Elements.   | Typical Formulas of Combination.                              | Heats of Formation in Calories at 15° C. |                |

(a) Precipitated. (b) From crystallized Si. (c) Not precipitated.

heats of formation of oxides and sulphides of the elements named. The heats expressed are in calories, obtained at a common temperature of 15° C., but the heats given are relatively true at the temperature of Bessemerizing copper matte.

The heat disengaged in the formation of silicon oxide, which amounts to 219·2 calories shows very clearly the important relation which that element bears to the working of the copper converter. Applying the figures of the table to the following reactions, are obtained:—

It is evident that these reactions are produced in the converter through the combinations of air and sulphur. The heats of formation of the silicides have not yet been measured, nevertheless it is easy to understand that the copper does not

<sup>2</sup> *Mémoires de la Société des Ingénieurs Civils de France*, 6, 2, 1903.

slag so much while sulphur remains in the matte, for the sulphur helps the iron to transform copper oxide into sulphide at the moment it is produced, the reactions of which follow:—

Passing now to the last period of the operation where the sulphide ( $\text{Cu}_2\text{S}$ ) is transformed into copper, the final reaction follows:—

It is strongly exothermic and it is evident that it should be produced. But it is not produced directly and it must be admitted that it is produced by reactions analogous to the English reverberatory method.

This reaction is endothermic, which is explicable because in the English method after having permitted the material to oxidize itself it is given another heat. In the converter the mass re-heats itself at each instant by the formation of the same oxide,

Multiplying this second equation by 2 and adding it to the first we have

which after simplifying the preceding equation becomes

In closing it is noted that the mass can still gain temperature by the formation of slag.

A part of the foreign metals disappears in consequence of the physical phenomenon called volatilization. The anhydrides of arsenic and antimony volatilize, the first passing into the state of vapor without decomposition at  $200^\circ\text{C}$ ., the second decomposes to the red oxide and sublimes. With contact of air it can give the peroxide  $\text{Sb}_2\text{O}_3$ . The zinc can volatilize for the temperature of the converter is higher than  $1,000^\circ\text{C}$ . The vapors of zinc are oxidized and carried off. A part of the lead disappears also in the state of vapor. The temperatures of volatilization of a few metals are as follows:—

TEMPERATURE OF VOLATILIZATION OF METALS.

|                    | Degrees Centigrade. | In Vacuum. |           | Degrees Centigrade. | In Vacuum. |

**The Selecteur.**—The preceding thermo-chemical reactions account for the elimination and selection of the foreign metals as follows: The elimination of the foreign metals is accomplished partly by scorification, and an examination of the table of heats of formation shows that nearly all the bodies which figure there in passing from the state of sulphides to that of oxides disengage more heat than copper, therefore it is concluded that they oxidize first, followed by those which scorify, viz.: tin, zinc, lead, antimony and manganese. Moreover the oxidation and scorification of the foreign metals is not completely attained, and they remain partially in the white metal. Their elimination proceeds during the treatment of white metal in the furnace and proportionately as the copper is rendered nascent it will precipitate them from their sulphides at least those which disengage less heat of formation than the copper by the reactions—

It is seen, therefore, that the sulphides of nickel, cobalt, lead, silver and antimony should be decomposed, and also that a very small portion of copper desulphurizes a large proportion of these metals. This precipitation of the foreign metals has been adapted to a number of enterprises to purify mattes from arsenic and antimony by means of iron or lead.

**The Neill Process for Leaching Copper Ores.**—The Neill leaching process is based on the use of sulphurous acid for the recovery of copper from the oxide and carbonate ores. These minerals are reacted upon by sulphurous acid with the formation of cuprous sulphite ( $\text{Cu}_2\text{SO}_3$ ), which is not soluble in water, but is soluble in water containing sulphurous acid—that is, the leaching solution must have an excess of the acid in it over that required to produce the reaction. The copper is precipitated by driving off the excess of acid by heat. The precipitate is cupro-cuprous sulphite ( $\text{CuSO}_3 \cdot \text{Cu}_2\text{SO}_3 + 2\text{H}_2\text{O}$ ) and contains 49.1% Cu. It is a heavy, crystalline compound, of dark-red color, which settles readily from the solution and can be washed by decantation, dried and reduced to metallic copper by fusion on the hearth of a reverberatory furnace. Very small amounts of other metals are dissolved and the product is very pure copper. In practice the ore is crushed to pass a 20-mesh sieve, put in covered tanks and kept in a state of agitation while a current of sulphurous acid from the generators is forced through it. The copper will pass into solution in from one to four hours. The solution is drawn off through a filter press to separate the slimes. The latter and the sands are washed once with water, which is used over with the next charge. The solution in the precipitating tank is heated with exhaust steam, precipitating the copper salt. The plant can be arranged to save nearly all the sulphurous acid except that combining with the copper. One pound of sulphur is required to convert four pounds of copper into sulphite, or, with the loss from the excess, one pound converts three pounds. The sulphurous gas can be obtained either by burning pyrite or sulphur. Roasting a copper sulphide ore to an oxide will provide ample acid for its treatment. A test on a mixture of copper carbonates and some oxide in a siliceous ore gave 95% extraction. The advantages of the process over the sulphuric or hydrochloric acid method are: (1) Cost of

the chemical is low. (2) It is generated on the spot by the use of a very simple plant. (3) A relatively small amount of the chemical is used. (4) The copper is separated from the solution by heat alone. (5) The copper produced is practically free from impurities.

*Reactions of the Ziervogel Process.*—Robert H. Bradford<sup>3</sup> discusses in detail the reactions and temperature limits of the Ziervogel process, the investigation being confirmed by various exhaustive experiments. The author finds the range of temperature necessary for the process to be between 655 and 800°C., and that care should be taken to avoid heating to 850°C. Above 655°C. the silver sulphate is in the liquid state. Copper sulphates require 700°C. for their decomposition.

*Apparatus for Casting Metal.*—For casting metals, J. B. F. Herreshoff has patented a device<sup>4</sup> consisting of the combination of a series of molds, each having a liquid-circulating system, with means for causing the said molds to travel in a closed path, a stationary platform supported within the path of travel of the molds, a water-supply pipe forming the pivot of the system of molds, located beneath the platform and in liquid-conducting communication with the liquid-circulating system of the molds, a furnace or other source of molten-metal supply, and a trolley-supported ladle arranged in operative relation with the furnace and the moving molds.

*Electrolytic Copper Tubes.*—During 1901 the English Electro-Metallurgical Co., which some time ago acquired the English works and patents of the Elmore copper tube process, produced an average of 25 tons of copper tubes per week. The improvement on the process by the late M. Secretan, in France, induced the owners of the French patents to acquire and operate the English patents also. The company expects to increase the output of the plant to its designed capacity of 60 tons per week as soon as it shall have been placed on the Admiralty list of contractors, the Board of Trade's requirements as to quality complied with, and the points in dispute between the vendor syndicate and the company settled.

#### PROGRESS IN THE ELECTROLYTIC REFINING OF COPPER IN 1901.

BY TITUS ULKE.

*Electrolytic Copper Refineries.*—The subjoined carefully compiled statistical table gives the principal data required for determining the present status of the electrolytic copper refining industry in the United States. About 576 tons of electrolytic copper are produced in this country daily, or 210,240 tons annually, valued approximately at \$67,768,762. The by-product recovered daily contains about 53,187 oz. silver and 501 oz. gold, which makes an annual output of 19,413,255 oz. of silver, valued at \$11,444,114. and 182,865 oz. of gold, valued at \$3,779,820.

During 1901, ten copper refineries were in operation in the United States. The electrolytic works at Irvington, N. J., of Glorieux & Woolsey, known as the Irvington Smelting & Refining Co., was shut down in 1900 to be dismantled, while the new plant of the De Lamar Copper Refining Works, near Cartaret, N. J., is in course of construction.

<sup>3</sup> A paper read before the American Institute of Mining Engineers, May, 1902.

<sup>4</sup> United States Patent No. 660,696, filed March 12, 1901.

The Perth Amboy plant (Guggenheim Works) of the American Smelting & Refining Co. has been enlarged so that 150 tons of electrolytic copper can be handled in it, instead of its former capacity of 50 tons. It is expected to operate only about two-thirds of the capacity, the remaining one-third being held in reserve. This will explain the surplus of generator power as compared with the actual daily output.

At the Buffalo Copper Works, about 60% of the Calumet & Hecla Co.'s enormous production of native copper concentrates is refined, the argentiferous copper material running over 20 oz. silver being melted down and cast into plates, which are sent to the electrolytic works.

Practically all of the silver in the crude copper passes into the slimes or tank-mud, and is periodically recovered by boiling the silver-mud with sulphuric acid

to remove the bulk of the impurities, refining it on a small furnace-hearth and casting the silver into bars weighing about 1,000 oz. each. The absence of gold from the argentiferous copper obtained by reducing the native copper ores of Michigan is remarkable and greatly simplifies the silver parting process.

The new 40-ton electrolytic copper refinery, built east of the old works, is furnished with power by a McIntosh-Seymour engine, driving a Crocker-Wheeler generator, which is guaranteed to deliver a current of 300 volts and 1,700 amperes when running at a speed of 126 revolutions per minute. There are 490 tanks in the new refinery, with a basement underneath the tank floor to facilitate inspection for leakages and emptying of the tanks. The circulation of the electrolyte is effected by a cascade arrangement of the tanks instead of on a level, as in the old refinery, the solution being pumped to the highest row of tanks. The anodes measure 29 in. long, 27 in. wide, and about 1 in. thick, and are provided with small lugs on top instead of large side lugs, which were formerly used. Electric traveling cranes and racks similar to those in use at the Perth Amboy refineries, will be used for charging the tanks with plates and removing the cathodes.

Each heat of refined copper is tested for the mechanical properties, and for the electrical conductivity of the copper as follows: Representative sample bars, weighing about one pound each, are cast at the pouring of every furnace charge. Pieces of sufficient length from these sample bars are passed through small rolls and annealed at a dull red heat in the muffle of an assay furnace whenever they become too hard. They are then pickled in dilute sulphuric acid, washed in water and passed through successive dies, finally being drawn into wire about 0.125 in. in diameter. These wires are numbered, and constitute the samples used in the Siemens' apparatus for making the conductivity tests. Good annealed copper wire 0.125 in. diameter should possess a conductivity of at least 98%, should stand about 55 twists before breaking, and should show a tensile strength of not less than 24 tons per sq. in. of cross section, according to the usual standard.

The cost of electrolytic refining at the Buffalo works I estimate not to exceed 0.3c. per lb. of crude copper, with current delivered at a cost of \$27 per H.P. per year.

*Cowper-Coles Centrifugal Copper Process.*—S. O. Cowper<sup>1</sup> covers an improvement in the process of electro-deposition on rapidly rotating mandrels, by projecting the electrolyte tangentially against the mandrels. He claims the deposition of copper absolutely free from lamination at the high rate of 200 amperes per sq. ft. of cathode surface, in making 12-in. diameter tubes, the gas bubbles or suspended impurities being thrown off by centrifugal force. The cathode is rotated at a speed up to 1,000 revolutions per minute, and a current density of 170 amperes per sq. ft. cathode surface is preferably employed. The electrolyte is preferably kept at a temperature of 160°F.

The following advantages are claimed by Cowper-Coles for his process: 1. Rapidity of action five times as great as the ordinary electrolytic processes. 2. Less plant and floor space. 3. Cheaper. 4. Sheets and tubes free from lamination. 5. Less waste of copper and high grade of product.

---

<sup>1</sup> British Patent No. 9,731, of 1901

This process certainly appears to lack novelty, for the reasons given in THE MINERAL INDUSTRY, Vol. IX., page 229. The apparatus, moreover, in its present shape, as disclosed in the patents is too complicated and is in other respects not fully suited to the electrolytic refining of argentiferous copper commercially.

The apparatus employed for the centrifugal process<sup>2</sup> consists of a wooden vat in which are placed crude copper anodes; the cathode is a hollow brass mandrel supported on a revolving shaft, the latter being brought through the bottom of the vat to the top, and protected from the copper sulphate solution by a lead-cased cast-iron column. The shaft is revolved by gearing placed beneath the depositing cell, the speed varying with the size of the mandrel employed. The mandrel at one end is fitted with an eye bolt with which to lift it, and a circular brass casting against which the contact brushes rub for collecting the negative current. The brushes are fitted to arms which are made to turn backward to allow of the easy insertion and withdrawal of the mandrel. To prevent the electrolyte being carried round with the mandrel it is found necessary to have baffle plates made of insulating material. A baffle plate is also placed at the bottom of the mandrel to prevent the formation of copper trees or nodules. The electrolyte is briskly circulated through the cells by means of an acid proof pump, the solution being forced or pumped into a reservoir, where it passes through a filter to rid it of all suspended impurities. When it is desired to obtain a sheet of copper, the tube after being removed from the mandrel is cut, flattened out and annealed, while for wire, a piece of insulating material is wound round the mandrel in the form of a spiral and the copper deposited between the threads until its thickness is about equal to the distance between the threads. The spiral of deposited copper is then removed and, after annealing, is drawn down in the usual manner.

*Keith's Electrolytic Process of Recovering Copper.*—Dr. N. S. Keith's process, as carried out recently at Arlington, N. J., on ore containing from 1.5 to 2% Cu, is essentially one of crushing, roasting, leaching and electrolyzation, the copper being finally deposited on the cathodes in the electrolytic tanks.

The special feature in this process lies in the peculiar arrangement of the electrodes so as to prevent the deposition of spongy copper by insuring a retrogressive decrease of current density at the electrodes of each tank after the first, the number of electrodes per tank being increased progressively from the first to the last tank of the series employed. In this way the amperes of current flowing through each tank, which is connected in series circuit with the one adjoining, is kept the same, while the current density at the electrodes, which are connected in multiple in each tank, is decreased from the first to the last of the series of tanks, to compensate for the decrease of copper in the electrolyte in its course through them. Thus the current density may be from 15 to 20 amperes per sq. ft. of cathode surface with a 6% Cu solution, and 3 amperes per sq. ft. with a 0.5% Cu solution, provided a sufficiently rapid circulation of the electrolyte be maintained. The density of current in each tank must not exceed the limit required for the deposition of reguline copper.

*Electrolytic Production of Cathode Plates.*—E. G. Elliott and V. Kishner,

---

<sup>2</sup> Private communication from Mr. Cowper-Coles.

Perth Amboy, N. J., patented<sup>3</sup> a metallic cathode for receiving movable sheet-metal deposits upon both of its sides throughout its immersed surface, said plate being partially immersed in an electrolytic solution from which the metal may be deposited from a suitable anode, and with a scratch-groove upon its exterior, whereby the metal electro-deposited is rendered separable along the line of the groove during deposit.

*Forms of Cathode Plates.*—W. A. McCoy, of Perth Amboy, N. J., secured a patent<sup>4</sup> for an improved form of cathode plate, the object of which is to avoid the expense of the wooden cathode-frames heretofore commonly used on cathode plates to prevent the metal deposited upon one side of the cathode from becoming inseparably connected with the deposit upon the opposite side. At or near the lateral edges and bottom to facilitate stripping at opposite sides of the plate, are a series of recesses in the face of the plate, which form receptacles for any suitable insulating or non-conducting material. These recesses or receptacles are preferably perforations extending through the plate from side to side, and separate and apart from one another so that the insulating material will remain therein with security and not be detached under the rough treatment to which the more or less heavy plates are subjected when they are handled. The perforations are quite close together, so that the exposed metal between them will form but very slight connections of the deposited sheet with the metal deposited at the outside of the series of perforations, and thus the deposited sheets may be easily stripped from the cathode-plate, the sheet being easily torn or severed from the edge of metal in the act of stripping. The edge-deposited pieces may be easily removed from the cathode-plate after stripping and used as scrap metal. In practice the holes are usually drilled 0.25 in. in diameter and 0.2509 in. ( $\frac{1}{4}$  in.) from center to center. The insulating compound may be of any insulating material capable of withstanding the action of the electrolyte. The recesses at the sides and bottom of the plates may be continuous.

*Casting Machines and Conveyors.*—At the Raritan Copper Works, the anode casting machines are provided with a knocker wheel, which actuates upon a pin and thereby lifts the anode plate, weighing about 400 lb. from the mold. The wire-bar molds are ingeniously dried by jets of air issuing under 3 or 4 lb. pressure against the surface of the molds.

Walker casting machines are now being constructed so as to allow of being operated electrically instead of hydraulically or by compressed air.

In addition to the McCoy wire bar and the Walker ingot and anode casting machines, which have both been well illustrated and described in THE MINERAL INDUSTRY, Vols. VII. and IX., the Dyblie wire bar casting machine needs to be briefly noted. This machine is the invention of J. A. Dyblie, of the Illinois Steel Co., and was installed in the Anaconda, Mont., smelting plant some time since. The molds reciprocate on tracks over the tank, being overturned by means of a hand wheel to discharge the castings into the water. The overturning of one mold brings the next up into pouring position. Each end of the tilting furnace has its casting machine and tank, one ladle supplying each machine in turn. The castings are removed from the tank by means of an endless chain conveyor

<sup>3</sup> United States Patent No. 688,963, of Oct. 12, 1901.

<sup>4</sup> United States Patent No. 684,291, 1901.

working in it. It is reported that castings made by this machine from the tilting furnace are free from pin holes and seams, and that the time occupied, and the men employed are about one-half of former hand ladling practice.

*The Formation of "Trees" and "Nodules" in Electrodeposition.*—Mr. J. W. Swan has found that regularity and smoothness of deposit were almost entirely dependent on the absence of solid particles held in suspension in the electrolyte, and that excrescences could be entirely avoided by freeing the electrolyte from floating particles. It has been observed that each nodule was formed around a speck of some foreign substance.

*Corrosion in Depositing Copper.*—H. Sayer and F. S. Spiers<sup>6</sup> define corrosion as meaning the dissolving away of the copper, both anodes and cathodes, on account of the ordinary chemical action (really "local" action) between it and the electrolyte, and quite apart from the action of the current itself. The gradual effect of this corrosive action is to supersaturate the electrolyte with copper and thus cause copper sulphate crystals to separate out—a consummation most earnestly to be avoided. The superfluous copper is usually removed by electrolyzing with lead anodes.

It is a disputed point whether an acid solution of copper sulphate really does dissolve pure copper without the presence of air. Schuster's experiments<sup>6</sup> certainly point to the fact that nearly the whole of the corrosive action is due to the presence of oxygen in the solution—thus,

but Foerster and Seidel<sup>7</sup> categorically deny this, and declare that copper is soluble in copper sulphate even without the presence of air, the solubility increasing with the concentration. Copper, however, is quite insoluble in normal sulphuric acid at 100°C. It is probable that the prime action of the copper is to reduce some of the cupric to cuprous solution, and that this latter is subsequently oxidized by the air to the cupric form. The matter bears so far on practice that in many processes the electrolyte is either violently agitated or else air is forced through it; in such cases the corrosion of the cathode is doubtless higher than if the solution were at rest. In the case of the impure anodes, corrosion takes place even without the presence of air and corrosion of cathodic copper may take place indirectly under certain conditions—namely, in cases where cuprous oxide is deposited with the metal and dissolved in the electrolyte, forming a cuprous solution which may eventually be oxidized to cupric sulphate.

T. Gray, in his paper, "The Application of Electrolysis to the Standardizing of Electric Meters," has carefully studied the corrosion of electrolytic copper under various conditions of acidity, temperature, etc., for the purpose of determining to what extent the variations of the apparent electro-chemical equivalent of copper are due merely to the metal being redissolved. He found that the losses were very variable and indefinite, but seldom exceeded 0.000005 g. per sq. cm. per hour.

As would be expected, the values decrease with rise of temperature, and with

<sup>6</sup> *Electrochemist and Metallurgist*, April, 1902, p. 103.

<sup>6</sup> *Proceedings of the Royal Society*, 1894.

<sup>7</sup> *Zeitschrift fuer Anorganische Chemie*, 1897, XIV., p. 106.

diminishing current densities. Experiments indicate that while corrosion at ordinary temperatures is almost negligible, it increases as the temperature rises. The corrosion varies with acidity, but on the whole, the variations are not very considerable; however, at 50% acidity, and at a temperature of 80°C., the copper begins to be very rapidly attacked. The increase of weight in the neutral solution at 80°C. is due to the formation of a film of cuprous oxide,  $\text{Cu}_2\text{O}$ .

*Arrangement of Plant.*—A. L. Walker has obtained a patent<sup>9</sup> for a plant for electro-deposition of metals, especially copper. It specifies a plant for the deposition of metal electrically by means of heavy currents distributed through numbers of plates arranged in multiple in tanks arranged in series, embodying tanks arranged with the proximate walls substantially parallel and close together; leading-in and leading-out mains extending to the end tanks of series, said mains being of large and sufficient cross-section to carry the entire current supplied to all the tanks, distributing-bars of small cross-sectional area supported between adjacent tanks, and anodes and cathodes arranged in the tanks and having supporting projections at the top, the supporting projections of the anodes and of the cathodes in adjacent tanks resting freely on the same distributing bars whereby electrical connection between anodes and cathodes of adjacent tanks is established through connections individually of small and insufficient area to carry the total current but collectively of an area sufficient to carry said current, the supporting projections at one side of the anodes of the first tank and of the cathodes of the last tank resting freely on the leading-in and leading-out mains respectively.

The De Lamar plant, near Cartaret, N. J., has agreed to pay a royalty for the use of this arrangement in its electrolytic department.

*Electrolytic Process of Making Copper Sulphate.*—H. Palas and F. Cotta, Marseilles, France, obtained a patent<sup>10</sup> for the process of producing metallic sulphates and simultaneously obtaining an alkaline base as a by-product by electrolysis, said process consisting in separating the anode and cathode by a porous diaphragm, supplying a stream of the electrolyte solution of an alkali-metal sulphate to a soluble anode of the metal to be transformed into sulphate, supplying another stream of the same electrolyte solution to the cathode on the other side of the diaphragm and passing a current of electricity through the apparatus. In particular, a cathode of iron or other metal not attacked by alkalies, is surrounded with an electrolyte of sodium or potassium sulphate. In the anode compartment is an anode of the metal to be converted, surrounded with an electrolyte of its sulphate, *e.g.*, a copper anode in a solution of copper sulphate. The strengths and temperatures of the electrolytes should be such as to afford the least electrical resistance. On passing a current of 2.5 to 3 volts, the  $\text{SO}_4$  ion from the sodium or potassium sulphate passes to the anode side, and meeting the free copper re-forms copper sulphate. The  $\text{SO}_4$  ion freed from the copper sulphate attacks the anode, and so strengthens the anode electrolyte. Eventually a solution of caustic soda or potash is left in the cathode cell, and an enriched solution of copper sulphate, entirely free from alkaline sulphate, is obtained in the anode cell.

<sup>9</sup> United States Patent No. 687,800, Dec. 3, 1901.

<sup>10</sup> United States Patent No. 679,985, 1901.

*On the Crystallization of Copper Sulphate.*—In a series of experiments on the crystallization of copper sulphate, Arthur J. Hopkins<sup>11</sup> found that the size of the crystals was not dependent on the degree of concentration, nor on the relation of the size of the crystallizing vessel to the volume of the contained solution nor finally on the rapidity of cooling. In a solution supersaturated in absolute quiet, no crystals will form. Solutions of convenient concentration and volume were obtained when 171 g. copper sulphate crystals were dissolved in water and 15 c.c. normal sulphuric acid were added, the whole being concentrated to less than 340 c.c. and later diluted to exactly that amount with boiling water. The size of the crystals desirable for quantitative work was decided to be of a length of from 20 to 30 mm. and as the ratio of the volume of the solution to the horizontal surface of the containing crystallizing dish is identical with the depth of the solution for each volume, a dish was selected which would give a constant depth. A depth of 6 mm. was found to allow ample space between crystals 20 to 30 mm. long when crystallized from a solution of the strength indicated above. The diameter of the dish which will hold 340 cm. at a depth of 6 mm. is 26 cm. and, in general, for this depth, the diameter required is the square root of twice the contained volume. Under these conditions, the size of the crystals will depend upon the number of crystal points first started in the solution, as it cools beyond the saturation point. The number of these points depends upon the conditions obtained in the dish during the time of supersaturation, and they are formed by allowing a slight blast of cold air to impinge on the surface of the cooling solution, which operation is continued until the proper number has been obtained. Very little practice enables one to ascertain this condition from the spacing between the floating crystals rather than the actual number of them. For crystals of a different size a few tests will determine the proper spacing as well as the proper size of the crystallizing dish. In the opinion of Mr. Hopkins, crystals of any desired size may be obtained not only from the original solution but from all successive mother liquors.

*Use of Magnesium-Copper Alloys in Casting Copper.*<sup>12</sup>—Among the means commonly employed in casting to free copper from dissolved gases and cuprous oxide, magnesium occupies a prominent place. Its action is to unite with the free oxygen and the oxygen combined in  $\text{SO}_2$ ,  $\text{CO}$  and  $\text{Cu}_2\text{O}$  to form  $\text{MgO}$ , which yields a slag covering the molten copper. The slag is then skimmed off and the copper poured which gives a dense casting free from blowholes. The use of metallic magnesium for this purpose requires skill and care in order to avoid the violent sputtering of the molten copper, which might cause injury to the workmen. This disadvantage may be entirely obviated by introducing the magnesium in the form of an alloy with copper, such as the cheap 50 Copper-50 Magnesium alloy now produced in large quantities at Hemelingen, Germany. This alloy is reddish-gray in color and stellate in structure upon fracture. Its sp. gr. is 2.97, and it melts at  $450^\circ\text{C}$ . It is very brittle and may therefore be broken easily with a hammer into conveniently sized pieces. In most cases not more than 50 g. of the magnesium alloy is required to make a dense casting of 100 kg. of copper, but in practice it is best to add the alloy in portions of 20 g. until the desired action

<sup>11</sup> *American Chemical Journal*, May, 1901.

<sup>12</sup> *Chemiker Zeitung*, 1901, Report 123.

secured. Higher proportions of the alloy than those stated increase the hardness and consequently the resistance of the copper and may be used in improving quality of brass, bronze and similar alloys.

**Copper Wire for Power Transmission Lines.**—Dr. Bell<sup>13</sup> states: "At present best grades of standard copper wire have a conductivity of fully 98% that of the chemically pure metal, and even this figure is frequently exceeded. On account of the comparatively low tensile strength of copper—ordinarily about 100 lb. per sq. in.—efforts have been made to exploit various alloys of copper on the theory that their greater strength would more than counterbalance the reduced conductivity and increased cost, by enabling less frequent supports to be used. Aluminum bronze, silicon bronze and phosphor bronze have been tried, together with some other alloys of a similar nature. . . . Copper which is hard-drawn has a greater tensile strength than any so-called bronze of similar conductivity—from 60,000 to 70,000 lb. per sq. in.—with a resistance less than is in excess of that of ordinary copper. The following table gives the conductivities and tensile strengths of some of the various materials used or proposed for live wires, pure copper being taken as the standard at 100% conductivity.

| Material.                   | Conductivity. | Tensile Strength.<br>Pounds. |
|-----------------------------|---------------|------------------------------|
| Commercial copper wire..... | 98 to 99      | 35,000                       |
| Hard-drawn copper.....      | 96 to 97      | 60,000 to 65,000             |
| 1. Silicon bronze.....      | 97            | 68,000                       |
| 2. Silicon bronze.....      | 80            | 70,000                       |
| 3. Silicon bronze.....      | 45            | 110,000                      |
| Phosphor bronze.....        | 26            | 101,000                      |
| 1. Annealed wire.....       | 14            | 55,000                       |
| 1. Carbon steel wire.....   | 10 to 12      | 120,000 to 130,000           |

"It is evident that where the best combination of strength and conductivity is wanted, hard-drawn copper wire is unexcelled. For all ordinary line work hard-drawn copper wire is amply strong; it is, besides, easier to manipulate than a wire of greater hardness. Occasionally, where it is desirable to use extra long spans, or excessive wind pressure is to be encountered, the hard-drawn wire is preferable."

**Manufacture and Use of Silicon-Copper.**—The Cowles Electric Smelting & Aluminum Co., Lockport, N. Y., makes silicon-copper in the electric furnace, and claims to be the only maker of pure silicon-copper, also that the metal made by the Waldo Foundry Co. and the John A. Roebling's Sons Co. is more properly silicon-bronze, made by adding silicon-copper to pure copper.

O. J. Steinhart, however, affirms that copper silicide is being produced by the Fabrik Electrometallurgischer Produkte, at Frankfurt-on-Main, Germany, with 5%, 15% and 30 to 35% Si in the shape of ingots weighing from 15 to 18 lb., which are divided by notches, so that they can be easily broken into smaller pieces. Among the uses for copper silicide are: 1. In place of copper phosphide as a purifying and deoxidizing agent, acting as a reducing medium should any of the oxygen compounds of arsenic and antimony be present, and thereby counteracting their deleterious effects. The resultant metals combine with the metallic copper, whereas the silicon employed does not enter into combination with it.

<sup>13</sup> *Electric Transmission of Power*, pp. 869-873.

If copper is therefore finally refined with copper silicide, a greater strength and toughness is imparted to it.

2. Silicon may also be added to copper in such a manner that it forms a permanent compound with the latter, thereby adding materially to its hardness and strength, which can be made equal to that of steel if a sufficiency of silicon is incorporated with it. Small quantities up to about 0.1% render it particularly suited for telephone wires, and other electrical purposes, as this alloy possesses a far greater strength than ordinary electrolytic copper wires.

The subjoined table gives figures showing the relative conductivity and tensile strength of pure copper and these alloys:—

| Material.                              | Tensile Strength,<br>per sq. mm. in kg. | Conductivity. |
|----------------------------------------|-----------------------------------------|---------------|
| Pure copper wire.....                  | 28-35                                   | 100           |
| Cu with 0.02 to 0.05% Si.....          | 45                                      | 98            |
| Cu with 0.05, 1.1% Si and 1.1% Sn..... | 88                                      | 48            |
| Cu with 0.5% Si.....                   | 50                                      | 28            |
| Cu with 3.5% Si.....                   | 95                                      | 7             |

These alloys are particularly suited for bolts in locomotive fire-boxes, for rivets, wire ropes, etc.; that is, in all cases where high tensile strength and small elongation are required and iron is not admissible, as well as those in which an acid-resisting material should be employed.

3. Copper silicide forms a very useful addition to tin and zinc bronzes in place of copper-phosphide. The bronzes thus prepared are very elastic and heat resisting, much less silicide being required as compared with the corresponding phosphorus compound. The purifying power of 10% silicide as compared to the same strength phosphide is as 1.48:1, or entails a saving of about half the material when the former is employed.

4. As an addition to aluminum bronzes it should be of great importance, as alloys can be obtained with high tensile strength, ranging with respect to their hardness from ordinary brass to the hardest phosphor bronze. The manufacturer, therefore, has a very convenient means of preparing his alloys for any specific purpose. If, for instance, aluminum bronze of great strength is required, being soft at the same time, the chilling of the alloy when red hot is advisable. Generally speaking, the presence of silicon in aluminum bronzes, such as the Heroult and Cowles bronzes, increases their strength and hardness, and at the same time reduces their elongation.

With reference to the quantity of copper silicide required for these various purposes an exact rule cannot be laid down, as this depends upon the object to be attained and the material employed, but in most cases from 50 to 100 g. per 100 kg. will generally suffice for copper alloys and bronzes.

*Determination of Oxygen in Commercial Copper.*—Maurice Lucas<sup>14</sup> states that oxygen is generally estimated in copper by two methods, *viz.*, reduction by hydrogen and measuring the loss of weight, which represents the oxygen and the volatile metals; or by treatment with silver nitrate and estimation of the copper in the residue. A third method has been devised which consists in melting the copper with tin in the electric furnace in a current of carbon monoxide; the

<sup>14</sup> *Bulletin Société Chimie*, 23 (24), 900-004.

carbonic acid formed is then collected and weighed. The copper and the quantity of pure tin necessary to form a 20% alloy are placed in a tared porcelain boat in the cool part of a porcelain tube, and the CO gas passed over it for 15 minutes; the potash and sulphuric acid bulbs, previously weighed full of air, are then attached to the tube. The latter is then gradually moved until the boat is in the hot part and the temperature is maintained at 900°C. for an hour. The bulbs are then disconnected and weighed again full of air. The boat is allowed to cool by moving the porcelain tube back to its original position, and the boat is finally weighed. In this manner is obtained first, the weight of CO<sub>2</sub> formed, which multiplied by 0.364 gives the oxygen set free, and secondly, the loss of weight, which represents the oxygen and the volatile bodies, as arsenic, antimony, etc.

This method has been satisfactorily tested with pure cuprous oxide and with known mixtures of cuprous oxide, copper and tin. The effect of impurities was also determined by adding a mixture of copper arsenate, phosphate, etc., to the pure copper and tin in the boat. The method is said to be applicable to all metals whose oxides are reducible by CO.

*The Cyanide-Assay for Copper.*—H. H. Miller, in a paper read before the American Institute of Mining Engineers, November, 1901, states essentially that the amount of KCN necessary to decolorize a copper solution does not give the true amount of copper present in the ore or matter when these contain other bases which interfere with the assay. When the acid solution is precipitated with excess of ammonia, Ag, Ni, and Zn, if present in the ore, go into the solution, and react like copper with the KCN; while Fe, Mn and Al are precipitated as hydroxides. This precipitate invariably contains a small portion of the copper which, in the case of iron, is probably mechanically retained; but where manganese is present there is a further retention, possibly as a manganate. Arsenic may also form an insoluble arsenate; and Cr also interferes. Miller found that the amount of copper retained by these causes combined varied indirectly as the ratio of the total copper to the disturbing elements present.

In standardizing the KCN solution for any particular ore or class of ores of the same composition, two portions of 10 g. each are weighed out for separate assays. To one is added a weighed amount of pure copper, and the two are run through together, being treated in all respects like regular assays. The difference in the number of c.c. of KCN used in the two assays represents an amount equivalent to the weighed excess of copper taken, and from this the true value of the ore is readily ascertained. Operating on the same weight of identical gangues, this figure (with frequent checking) is used. For a different gangue, or a different weight of the same gangue, another test must be made; and whenever an accurate determination of a new ore is required, the assay is run in duplicate as above described.

If due attention be paid to the above details the cyanide method will prove superior to the iodide volumetric method. The latter is certainly no quicker, and consumes much larger quantities of chemicals, besides being subject to many sources of error. The colorimetric assay, an improved application of which has been described by Mr. J. D. Audley Smith,<sup>15</sup> is adapted to low-grade ores

<sup>15</sup> *Transactions of the American Institute of Mining Engineers*, Vol. XXX., 857.

only, and for these does not seem to possess any advantages over the cyanide method, either in point of time or accuracy of results.

By effecting the solution in acid on a thick asbestos pad, heated by gas- or gasoline-burners, a number of assays can be made at once, requiring little or no attention from the time they are placed on the fire until they are ready for the addition of ammonia. The mixed acid and dilute ammonia is kept prepared in quantity. For measuring out the portions of acid and ammonia for each assay, the most convenient vessel is a graduated cylinder of 100 c.c. capacity.

The cyanide method can be applied with equal success to richer ores, as well as to concentrates and mattes. For low-grade ores containing not over 1% Cu, the KCN solution should not be stronger than 1 c.c. = 0.005 g. Cu. For richer material a solution of twice this strength can be used to advantage.

*Determination of Copper by Precipitation with Aluminum and Electrolysis.*—The following quick and exact method for the quantitative estimation of copper in pyrites, impure matte, etc., is described by O. N. Heidenreich.<sup>16</sup> From 2 to 5 g. of the pyrites or similar substance, is dissolved in aqua regia, the nitric acid evaporated off, and the residue redissolved in 5 c.c. dilute hydrochloric acid and 10 c.c. water. The whole is washed into an Erlenmeyer flask, diluted to 100 c.c., and warmed with excess of sheet aluminum on the sand-bath. When the solution is colorless, showing that all the iron oxide is reduced, the solution is filtered, and the residue (copper and aluminum) is washed free of chlorine, the filter-paper burned, and the copper and aluminum dissolved in nitric acid. The copper solution thus obtained is finally subjected to the ordinary electrolytic assay.

*The Ferrocyanide Assay for Copper.*—F. Repiton<sup>17</sup> describes a method which is essentially as follows:—

To the neutral boiling sulphate solution to be assayed is added a decinormal solution of potassium ferrocyanide, until the characteristic blue end reaction is obtained with a few drops of a decinormal solution of iron sulphate, placed on a porcelain surface.

One c.c. N/10 potassium ferrocyanide = 0.0063 g. Cu, according to the equation:—

*Electrolytic Silver Refining.* The electrolytic silver refineries in operation in the United States in 1901 are given in the subjoined table:—

No gold bullion was electrolytically refined at the new mint at Philadelphia in 1901.

#### TREATMENT OF SLIMES FROM THE ELECTROLYTIC REFINING OF COPPER.

BY ROBERT L. WHITEHEAD.

THE slimes produced in the electrolytic refining of copper vary in precious metal content from 15,000 to 22,000 oz. silver and from 4 to 200 oz. gold per ton, the copper contained being from 10 to 40%, in the form of metal, copper oxide, copper sulphide and copper sulphate, the last-named combination being due to imperfect washing of the slimes.

The usual treatment of slimes in large smelting and refining works equipped with a desilverizing department is to add the dried slimes in paper bags of 10 or 15 lb. capacity to the charge of retort metal on the cupel hearth. The copper and impurities are oxidized and pass off in the slag, while the gold and silver is absorbed in the refined retort metal remaining on the cupel. The copper dross is treated in a shaft furnace for the recovery of the copper, antimony and lead, the copper being regained as copper matte.

In electrolytic copper refineries the slimes are treated by the sulphuric acid method, which is modified according to the character of the material. In ordinary practice, the wet slimes from the tank-room are dried in a centrifugal dryer having 30-mesh phosphorbronze screens in place of the usual filter cloth. The coarse particles of copper are caught on the screen, while the slimes pass through into a storage tank. In this treatment about 10% by weight of the slimes is separated as metallic copper very rich in silver which is added to the charge in the anode furnace. The slimes after settling are transferred to a large tank lined with 12-lb. lead and equipped with two steam coils extending its full length. Hot air is forced into the solution by an injector. Sulphuric acid in the proportion of 1,500 lb. of acid (66°B.) per ton of slimes is then added and the solution boiled from 10 to 12 hours, which results in the dissolving of most of the copper, 66% of the arsenic and all of the bismuth and iron. The supply of steam is then shut off and the solution allowed to settle. The supernatant liquor very rich in impurities is siphoned into storage tanks and subsequently transferred to the evaporators for the manufacture of copper sulphate crystals (blue stone). The tank is then filled with water up to the level of the original sulphuric acid solution, the steam is turned on and the temperature again raised to the boiling point. When this is done an addition is made of the settlings from the acid parting kettles which consist of metallic copper and considerable silver sulphate. The contents of the tank are then thoroughly mixed, the copper precipitates metallic silver from the silver sulphate solution being itself transformed to copper sulphate. The treatment continues until metallic silver is no longer produced. Should the silver sulphate be in excess of the corresponding quantity of copper needed to precipitate its silver content, a small addition of untreated slimes is made to supply the deficiency. The slimes are then washed several times by decantation, transferred to filters, and washed with boiling hot water. They are then transferred to cast-iron drying pans and dried in a furnace, the dried product being subsequently mixed with sand and soda ash and melted in a

reverberatory furnace capable of holding from 50,000 to 60,000 oz. of silver. The doré bars resulting from the furnace treatment assay from 950 to 960 fine in silver and from 10 to 20 in gold, the remainder being copper. The slag from the furnace melting contains 5 or 6% copper and 3 or 4 oz. silver per ton, the quantity produced depending upon the richness of the slimes. If the slimes are very rich the quantity of slag need not exceed 200 lb. per ton of slimes treated. The doré bars are placed in cast-iron kettles and parted by sulphuric acid (66°B.), similarly to the process in use at the New York assay office and at other Government refineries.

The cement silver is thoroughly washed with hot water, placed in a hydraulic press and pressed into cakes of 1,500 to 2,000 oz. weight which are removed from the press and charged without drying into a cupel furnace of 60,000 oz. capacity. A small quantity of niter is thrown on the metal to remove the tellurium contained in the silver. When this is accomplished the molten refined silver is cast into 1,200 oz.-molds. The refined metal varies from 998 to 998.5 in fineness.

The gold is transferred to small parting kettles and boiled with sulphuric acid (66°B.) to dissolve the remaining silver. When this is accomplished a few lumps of saltpeter are added to the solution and the boiling continued for two or three hours, to remove the small quantity of silver still contained in the gold and to coagulate the finely dissolved gold which is of advantage in diminishing the quantity of float gold produced in the subsequent washing. The gold is then dried, melted under borax and cast into bars of 993 to 996 fineness.

Generally in electrolytic copper refineries, the copper sulphate solution formed by the reduction of the silver sulphates is added to the copper electrolyte in order to utilize the free sulphuric acid which is present to the extent of from 8 to 10%. The impure solution from the slimes tank is concentrated by evaporation to 42°B. and crystallized, the crystals formed being purified by repeated solution and crystallization until of marketable purity. The mother liquor from the crystals contains about 40% sulphuric acid, which is utilized by heating in a lead pan to 60°B. and subsequent cooling in iron pans. During the cooling iron and copper are separated. The resultant acid solution is used either in parting the doré bars or in the first treatment of the slimes. The slags produced in refining the slimes are treated in several ways: 1. By addition to the slags from the anode furnace, which however has the objection that the resultant copper is very impure and must be separately treated in the tank-room. 2. By treatment in a shaft furnace with litharge which yields a copper matte and a silver-lead bullion. The latter is cupelled for silver, the litharge formed being used to treat another lot of slimes slag. 3. By mixing with soda ash and melting in a reverberatory furnace which yields a very clean slag and a very base bullion. This slag is sold to lead smelters as it contains less than 60 oz. silver per ton and practically all of the antimony and tellurium of the original slimes. The base bullion is treated by adding small quantities to the regular charge of the softening furnace. The last-named method is the one used at the present time by the Seattle Smelting & Refining Co., at Seattle, Wash., in the treatment of the slimes produced by the Amalgamated Copper Co.'s plants at Great Falls and at Anaconda, Mont.

PROGRESS IN 1900 AND 1901 IN THE MAKING OF BLUE VITRIOL BY  
HOFMANN'S METHOD.<sup>1</sup>

BY OTTOKAR HOFMANN.

THE original experimental plant that was constructed for the American Smelting & Refining Co., at Argentine, Kan., for the manufacture of blue vitriol has been repeatedly enlarged during the past few years until its present capacity is 60 tons per day, which makes it probably the largest blue vitriol plant in the world. The process has been modified and improved as experience has directed and the present paper gives the progress that has been made both in construction of the apparatus and in handling the material.

The material delivered to the blue vitriol section of the works for treatment consists almost entirely of leady copper matte as the process recovers the lead which is not the case when the matte is used to make copper anodes. The matte containing about 40% Cu and from 12 to 14% Pb is pulverized through a 50-mesh screen in a Krupp ball mill of 100 tons daily capacity and the fine product is roasted in 3 two-story Pearce turret furnaces, each provided with three fire-places at the lower and two at the upper hearths. The newly constructed furnace, which is 40 ft. in diameter, has a larger capacity than either of the older ones, and the feeding of the matte as well as the filling of the coal hoppers over each fire box is accomplished by mechanical contrivances. Slack coal is used as fuel and is burned on step grates. Great care is exercised in roasting the pulverized matte, both to avoid the formation of hard lumps which easily occurs with leady matte if the temperature is not well regulated in the beginning of the roasting process, and to prepare the matte properly for the subsequent treatment with diluted sulphuric acid. These conditions call for the conversion of as much as possible of the copper into oxide and sulphate, while the iron should be changed to red oxide which is only slightly soluble in hot diluted acid. The three furnaces are discharged into a common conveyor having a water-cooled bottom. The cooled material is passed through a ball mill to reduce it a second time to the fineness of a 50-mesh screen and the re-crushed material is conveyed to storage bins. The dissolving is done in eight agitating or stir tanks which are arranged in two parallel rows with a track between for the delivery of the matte. The cross section of a tank 12 ft. in diameter and 6 ft. deep is shown in Fig. 1. The bottom and sides are lined with boards for protection against wear from the friction of the pulp. In the center is suspended a heavy wooden shaft having fastened to the lower end by heavy brass plates, a cross-beam cut at both ends like a propeller-blade. In the center and fastened to the bottom of the tank is a cone-shaped projection constructed of strong wooden staves, the interior of which is filled with sand. This cone forces the matte toward the periphery, where it is subjected to the swift rotating motion of the liquor, thus preventing its accumulation in the central part where the motion is much less. Two outlet pipes provided with hard lead valves connect with the pressure tank. These are placed one above the other to permit

<sup>1</sup> This article is supplementary to Mr. Hofmann's monograph published in *THE MINERAL INDUSTRY*, Vol. VIII., under the title "Hofmann's Method for the Manufacture of Blue Vitriol." Patents for his process have been obtained for the United States, France, Spain, the United Kingdom, and Mexico.

the withdrawal of a portion of the liquor if desired, in which case the paddle is stopped and the residues allowed to settle. In the usual working of the tank, however, the lower outlet pipe only is used. The wooden ring attached to the

FIG. 1 STIR TANK ELEVATION AND SECTION.

rim of the tank prevents the splashing of the pulp. The tank and trestle-support are enclosed in a flat lead pan to collect any leakage. The upper end of the shaft is provided with a gear wheel to receive the power. In

, the stir tank is filled with water, the agitator set in motion, and the ed, followed by matte, until the solution finally becomes neutral. The onveyed to the tanks by a lead pipe which leads from the acid storage The matte is conveyed by a special car, the box of which is partly covered a slot at the dumping end for the gradual feeding of the material e box is brought to an inclined position. During the process the charge l by a jet of steam.

the stir tanks are two cast-iron pressure tanks into which the finished

FIG. 3 SECTION ON LINE A B

FIG. 2 PLAN SHOWING SIZE OF OPENINGS

FIG. 4 PLAN OF SUPPORTING FRAME

FIGS. 2, 3 AND 4.—CAST IRON PRESSURE TANK.

s drawn. On account of the residues the pressure tanks are in an position and are constructed as follows: The body consists of two cylind- ctions 4 ft. long and 4 ft. 6 in. in diameter, the bottom being of a section of 2 ft. 3 in. radius and the top rounding upward to a height above the rim. The sections are tightly flanged, with a rubber gasket

Four pipe connections are made through the top, the discharge pipe through the center passes nearly to the bottom and the filling pipe, air air outlet pipes are conveniently arranged around it. By proper con- with the filling pipe and by the use of valves, one pressure tank is made

to serve four stir tanks. The upper cylindrical section is provided with a man-hole, and the tanks are lined first with lead and then with wood to protect the lead from wear by abrasion. The air pressure required is from 40 to 50 lb. Fig. 2 shows a top view, and Fig. 3 a vertical cross section of an upright pressure tank, while Fig. 4 illustrates the supporting frame. This tank is somewhat smaller than those used at Argentine, and has one cylindrical section instead of two. The general arrangement, however, is the same. The air inlet extends downward along the side, ending near the discharge pipe, in order to keep the residues near the outlet in a loose condition and prevent the pipes from clogging. For this reason it is advisable to have a small stream of air enter during filling. The residues are rather heavy and pack tightly around the discharge pipe in quite a thick layer, which, on applying the pressure, would be forced in this compact condition into the discharge pipe and the pipe leading to the filter press, causing them to become clogged.

The pulp is forced by the pressure tank into a large filter press of which there are five in use. The press is 25 ft. long over all and has hard wood frames and plates 4 ft. square. The clarified solution flows from the press to a lead-lined tank from which it is elevated to the purifying towers by means of a pressure tank, the hard-lead pumps formerly used for handling copper solution having proved failures. The apparatus in which the refining of the solution is done has been simplified and its cost of construction greatly reduced. The lead and iron framework of the towers has been replaced with California red-wood which makes an excellent material to resist the action of hot cupric sulphate solution. The new towers, 9 ft. in diameter at the bottom, are constructed of staves 16 ft. long and 4 in. thick, which are well hooped with round iron; the bottom and top are flat. The towers are firmly fastened to a strong wooden trestle, which in turn is anchored to a concrete foundation. This construction is called for to guard against the oscillating movement of the tanks from the action of the contained solution, which is set in violent motion by the ascending air. Inside the tower, about 19 in. above the bottom, the 4-in. lead air pipe enters and is connected with a perforated 6-in. lead pipe which extends diametrically to the opposite side and is closed at the farther end. Outside of the tower the air pipe extends upward to above the top of the tower, and thence downward to the discharge pipe of an air compressor. This arrangement is necessary in order to prevent the solution from flowing to the air pump. At the same level with the air inlet, the 4-in. discharge pipe enters, which is provided with a hard-lead valve placed close to the outside of the tower. At about the same level a 1-in. steam pipe enters for heating the charge. The lead steam coil formerly used has been discarded and the heating is now accomplished by direct steam. This change was necessary as the lead coil required frequent repairs, and, moreover, the heating effect of direct steam is much greater than that of a steam-heated coil. The solution does not lose in strength through the condensation of the steam, the evaporation which is favored by the ascending air fully equalizing the dilution. The top of the tower is provided with an 8-in. pipe for the escape of the vapor and air, and with a 4-in. pipe for charging the crude solution. An opening in the center supports a small hopper which is filled with roasted matte, and by

FIG. 5

**HOFMANN'S TOWER FOR REFINING  
CUPRIC SULPHATE SOLUTIONS.**

lifting a cone valve the charging is kept under good control. By the action of the air and the cupric oxide of the roasted copper matte in the neutral solution, the impurities are oxidized and precipitated. The perforated cones, of which there were three in each tower for the distribution of the compressed air throughout the solution, have been replaced by a sufficiently large perforated pipe. This change simplifies the construction without impairing the efficiency of the tower. In charging the towers, room must be left for the increase in volume of the solution which occurs as soon as the air is supplied. A tower of the new type can be charged with about 5,000 gal. of solution, and as three such charges can be refined in 24 hours the working capacity of one tower is 15,000 gal. per day. Eight of these towers are in use at the Argentine plant. Fig. 5 shows a vertical section of a tower of the latest construction. The air inlet pipe, which is horizontal within the tank, has only its lower half perforated to prevent the inflow of matte and precipitate. The steam pipe was formerly inserted direct through the wood, but as the latter became affected by the heat, it now enters through the manhole cover. A similar effect was noticed with the bolts which passed through the wood to hold the flanges of the manhole, air inlet and discharge pipe. In the new construction these holes in the staves are cut much larger, and neither the frame nor the bolts are in contact with the wood. This is shown in the illustration. The two pipes are arranged in a similar manner. All iron parts on the inside of the tower are covered with heavy sheet lead.

When the reaction is completed and the solution freed from impurities, the charge is drawn off and forced through a filter press. The tower residues, consisting mainly of precipitated iron, arsenic, antimony and some undecomposed matte, contain also some basic copper sulphate. To remove the last named substance the residues are treated in a stir tank with a 2.5 to 3% cold acid solution, which dissolves the basic copper salt leaving the impurities unaffected with the exception of iron, which is acted on very slightly. The refined solution is conveyed to settling tanks from which the evaporating tanks are supplied.

The evaporating department furnishes the crystallizing department with about 90,000 gal. of concentrated solution daily. To supply this amount an improvement over the old pan evaporators with under-fire or steam coils was requisite, and as vacuum evaporators could not be adopted, I have introduced an economical and effective evaporator, which is illustrated in Figs. 6 and 7. The principles observed in the construction of this evaporator are the application of the hot furnace gases direct to the heating of the solution, and the almost complete utilization of the heat contained in them. The apparatus consists of a flat wooden tank with the exception of a 2-ft. space at the front end, which is made of steel, so that the wood will not be in too close proximity to the furnace. The tank is 65 ft. long, 12 ft. wide and 2 ft. deep, and is lead-lined, the two ends having much heavier lead lining than the sides and bottom. It is traversed longitudinally by 13 six-inch lead pipes, and rests on a wooden trestle-work of a proper height to correspond with the height of the furnace. At the furnace end in each lead pipe is inserted a 5-in. iron pipe 4 ft. long provided at the outer end with a flange. The iron pipes serve to protect the lead pipes from immediate direct con-

tact with the red hot gases from the furnace, they also make the connections between the lead pipes of the tank and the iron pipes of the furnace.

The furnace is comprised of the fire-place *C*, the dust chamber *D* and the heat distributing chamber *D*. At a proper height in the wall of the distributing chamber nearest the tank are 13 openings, in each of which is inserted a short cast-iron pipe, 5 in. in diameter with a flange at the outer end. Each pipe is connected with its corresponding lead pipe in the tank by a cast-iron S-shaped elbow *Y*, which allows the introduction of the compressed-air pipe *E* for removing any accumulation of ashes in the lead pipes of the tank.

An American underfed stoker is used for the slack coal fuel, and affords practically perfect combustion which is of great importance, as otherwise the lead pipes would soon become coated with soot and lose much of their efficiency to transmit the heat to the solution.

The opposite end of the lead pipes in the tank are connected with the brick suction chamber *O*, which in turn is connected by a galvanized iron pipe *R* with a suction fan *P*, the gases being discharged into the underground flue *S*. This flue serves in common to collect the waste gases from 11 evaporators, and terminates outside the building into a brick chimney 40 ft. in height.

The top of the pan is closed with a wooden cover and joists *G* are placed across the pan about 5 ft. apart, having cleats fastened to the lower side, as shown in Fig. 6. The spaces between the joists are covered with boards resting on the cleats and pushed close together, but not nailed, so that the whole or part of the cover can be easily removed. About 14 ft. from the front end of the tank is a 14-in. suction pipe *L*, connected with the main suction pipe *M*, which crosses all of the evaporators to remove the water vapors. This main suction pipe is constructed of wooden staves kept tight by hoops. The suction pipe *L* was first made of lead, but by some unexplained chemical reaction, it was destroyed after a few months of operation. Later a wooden tube was substituted, which was made in the same manner as the main tube. The latter is in connection with a large fan having the housing and wings of sheet copper and the shaft and arms of brass. This fan rapidly removes the vapor from each evaporating tank and by its use the building, even in cold winter weather, is entirely free from steam. A wooden stack serves for the discharge of the fan, and the strength of the exhaust is regulated by a wooden slide *N* inserted below the suction pipe *L*.

Close to the end of the evaporating tank, and resting on the cover is the lead-lined feed box *V*, from the bottom of which is a short pipe or nipple leading into the tank. The solution supply-pipe *T*, which crosses all the evaporators, is connected with the large supply tanks and serves to convey the solution to each evaporator by downtakes *U*. The outlet of the evaporating tank is in the side near the furnace end about 4 in. above the hot-air pipe *B* (Fig. 6).

The operation is conducted in the following manner: the pan is first filled to the level of the outlet with the copper sulphate solution to be concentrated, the fire is then started and the suction and stoker fans set in motion. The big copper fan is not started until the solution becomes hot enough to generate steam. During the operation the level of the solution is kept at the same height by the occa-

completely utilizing the heat generated. With the 65-ft. tank, the pipes at the exhaust end of the tank can be touched with the hand.

The greater economy and efficiency of this type of evaporator, as compared with one having a steam coil or bottom fire, is apparent. The production of steam involves a considerable waste of heat, and in using it to evaporate liquid, its circulation through coils produces a large amount of condensed water at a temperature very nearly  $100^{\circ}\text{C}$ ., the heat of which is generally lost. To evaporate by direct fire under the bottom of a pan is very inefficient and wasteful, and in the present case, in which no other metal but lead can be used for the pan, it requires great care and watchfulness to avoid melting the metal.

For concentrating chemical solutions which are not affected by iron as, for in-

stance, copper sulphate, the new evaporator described in detail above, can be constructed entirely of iron or steel and at much less cost. The pan itself, however, should always be placed in a wooden tank to prevent loss of heat by radiation.

The outflowing concentrated solution passes into a 6-in. lead pipe and is conveyed to a collecting tank, which is covered to prevent the cooling of the liquor. At Argentine, one pipe serves to collect and convey the concentrated solution from 11 evaporators. From the solution tank the hot solution is drawn into a horizontal pressure tank, and is elevated by compressed air to a system of troughs placed above the crystallizing tanks. The troughs are tightly covered with planks

to avoid cooling, which would cause crystals to form in them. In construction the troughs are of California red-wood, 10×11 in., in sections of 16 ft. The ends of the sections butt together and have an intervening rubber gasket. The sections are drawn together by iron flanges fastened to the sides of the trough a few inches from the end, iron bolts passing through both flanges. Brass screws are used in making the troughs, as iron nails or screws would not last. The joints between the bottom and the sides are coated with a fairly thick cement, which is made by boiling together waste rubber, resin, linseed oil, and ferric oxide. The cement when properly made should be quite liquid when very hot and stiff when cold, but never brittle or so hard that it cannot be kneaded between the fingers; nor should a piece of the stiff cement become liquid in water at a temperature of 80 to 90°C. The cement is elastic, and, as it never hardens, it keeps the joints well filled and overcomes the difficulty which arises from the shrinkage of one board from another. It has given very satisfactory results in the Argentine plant and there has been absolutely no leakage in the troughs, which in aggregate length amount to nearly half a mile.

The crystallizing department has 112 tanks, each of 720 cu. ft. capacity arranged in long rows intersected by several cross passages. Between each two rows is a track for transporting the blue vitriol crystals, on either side of which is a cement channel to receive and convey the mother liquor. The lead-lined wooden crystallizing tanks did not prove satisfactory, as the change in temperature caused by each filling with hot concentrated solution expanded the lead which did not subsequently contract in cooling; as a result in course of time the tank lining became wrinkled and broken, and caused leakage and expensive repairs. The entire floor of the blue vitriol plant is made of cement in order to collect any leakage that may take place. At present the tanks are made of concrete, and, though far superior to the original lead-lined wooden tanks, they do not come up to expectation because they also are affected by the sudden change in temperature when filled with the large bulk of hot concentrated solution. Although constructed with walls 20 in. thick, small cracks result, but leakage can be prevented by plastering a little cement on the outside of the tank. An experimental tank which has now been in use for several months seems to answer all requirements. It is built of bricks, having in the center of the walls a 2-in. space filled with a mixture of asphaltum and sand, which extends also from the sides under the bottom of the tank thus practically forming a tank by itself imbedded in the brickwork. When heated by the sudden filling of the tank with hot solution, the asphaltum softens, and when gradually cooled it contracts without cracking.

On the top of each tank are movable wooden frames supporting numerous strips of lead, on which the crystals form as well as on the sides and on the bottom of the tank. The solution remains seven days in the tank. At the expiration of this time the mother liquor is drawn off and the crystals removed. Ordinarily 16 tanks are discharged daily, but during the hot summer months more time has to be given for the crystallization, and fewer tanks are discharged and refilled daily.

The mother liquor is drawn off through a brass tube close to the bottom of the tank and flows in the above-mentioned cement channels in front of each row

of tanks direct to the three pressure tanks placed in a pit. These tanks elevate the mother liquor to large storage tanks, where it is mixed with fresh copper sulphate solution from the dissolving and refining departments, and is ready to supply the evaporators. When the crystallizing tank is empty, the movable frames with the lead strips and adhering crystals are lifted by a block and chain and the crystals knocked off with a wooden paddle. The crust of crystals from the sides is broken down. Rails are laid in recesses near the rim of the tanks so that the rails of the two opposite rows of tanks form a track for a hopper mounted on wheels. The crystals are shoveled with copper shovels into this hopper, which fills the push car underneath through a spout with slide in the center. As the tanks are 6 ft. deep, the crystals have to be thrown at least 7 ft. high, and in doing this work some of the crystals unavoidably fall back into the tank, fre-

FIG. 8.—DEVICE FOR REMOVING THE BLUE VITRIOL CRYSTALS FROM THE CRYSTALLIZING TANKS.

quently striking the shoveler. It was found that this was very injurious to the men, especially in summer, when they are dressed scantily and perspire freely. Their bodies became covered with deep sores, obliging them to be replaced by new hands. These sores were not dangerous, but were very painful, and the men naturally shunned the work. Finally this branch of the plant was closed during the months of July and August.

To overcome this very disturbing feature, I have constructed and set in successful operation the device illustrated in Fig. 8. On top of the hopper is mounted the frame *KK* with a turntable and circular track underneath which rests on a number of stationary wheels and is kept in place by the pin *P*. The object of this turntable is to make the apparatus available for opposite rows of tanks by rotation through 180°. The frame *K* is provided with a belt elevator *E* with

copper cups, which can be brought into a horizontal position by means of the shaft *F*. On the same shaft are the pullies *L* and *M* which drive the elevator pulley *N*. The lower end of the elevator is provided with the boot *B*, which can be brought down to within a short distance from the bottom of the tank and into which the crystals are shoveled. The power is imparted by an electric motor on the platform of the frame, which receives the electric current by an overhead wire with trolley extending along the rows of tanks. From the time this device was introduced the men were protected from the injurious effect of the blue vitriol crystals even during the hot summer months, as they had to shovel them only a short distance above the floor.

The push cars containing the crystals are wheeled to the sizing and drying department and lifted by a platform elevator to the rim of a bin, into which the crystals are dumped. From this bin the crystals are fed between a fast-revolving roll and a plate provided with teeth, which breaks the crusts of crystals without injuring the individual crystals. After passing the rolls the crystals drop into a small hopper having a short worm conveyor of copper at the bottom, which feeds a belt-elevator provided with copper cups. The elevated crystals drop into an inclined trough and are washed by a stream of mother liquor. They then drop into a hexagonal revolving screen having the shaft and arms of brass. The screen itself is of maple wood perforated with holes 0.375 in. in diameter. All crystals smaller than 0.375 in., together with the mother liquor, pass through a second inclined trough to another revolving screen, which is of sheet copper having 0.125-in. perforations. The mother liquor, with the very fine crystals, dirt, and sediment, after leaving the second screen is conveyed to an agitating tank and heated by a steam jet to dissolve the very fine crystals. The resultant solution is finally sent through a filter press, the clear liquor flowing to the storage tanks.

By using mother liquor to wash and screen the crystals, the fine crystals are as clean and pure as those of larger size. At the present time the blue vitriol crystals are dried in 10 brass centrifugal machines and conveyed to the storage bins.

The crystals, having been obtained from a neutral solution, are of a very deep blue permanent color which is not affected by light except in the direct rays of the sun. They do not change into a bluish white powder, which is the case with crystals made from an acid solution.

## COPPERAS.

THE production of copperas in the United States during 1901 was 23,586 short tons, valued at works at \$112,366 against 12,374 short tons valued at \$96,517 in the previous year. These figures do not include the quantity calcined for the manufacture of pigments, which is reported under production of "Iron Oxides."

Ferrous sulphate ( $\text{FeSO}_4, 7\text{H}_2\text{O}$ ) or as it is technically called "copperas," is produced in the United States principally as a by-product of the wire and sheet steel industries of the country. The wire, rods and sheets are subject to a bath of dilute sulphuric acid for the purpose of cleaning and brightening the metal. This bath is used until it accumulates a large quantity of loose particles of metal, etc., when it is replaced by a new mixture. The waste pickling liquor is allowed to flow away as much as possible, but in thickly settled communities this is opposed on the ground of injury to sewage pipes, contamination of water supply, etc. In some places this waste acid is not allowed to enter any waterway, although some authorities claim that it is beneficial to a stagnant flow. In localities where this waste acid is not allowed to flow away, iron and steel manufacturers utilize it for making copperas. The usual method followed is to collect the waste acid from the different pickling rooms into convenient tanks or reservoirs, later removing it in lead-lined tank cars or by gravitation through pipe lines to the works (for treatment) which must be located outside the busy portion of the community on account of the acid fumes produced. When received at the copperas works, the liquor is tested to ascertain its percentage of iron, acid, etc., and suitable additions are made in order to form a liquor of proper composition and strength. It is then run to large boiling tanks for the purpose of evaporating the excess of water which requires from three to four days to bring it to the proper strength for crystallization. The hot liquor is then drawn off into large vats or crystallizers and allowed to cool. The crystals form on the sides of the vats or on iron rods suspended therein and requires from three to ten days, according to the temperature. The crystals are then detached and submitted to an additional drying process in order to eliminate any surplus moisture, and when this is done they are ready to be packed in barrels and marketed.

Copperas crystals are used in the manufacture of inks and blues, for polishing plate glass, for dyeing cottons and woolens, and in different branches of the chemical trade.

The bottom settlings of the tanks are taken by some of the manufacturers and calcined in furnaces with the aid of lime or similar material to make Venetian reds, Indian reds and iron oxides. The bottom salts are also used to some extent as a fertilizer and disinfectant, as a precipitant in some forms of chemical treatment of sewage and in gas works for purifying purposes.

The largest producer of copperas is the American Steel & Wire Co., whose plants are operated in connection with the manufacture of wire at Worcester, Mass., Cleveland, O., De Kalb and Waukegan, Ill. Among the other producers are the Pennsylvania Salt Mfg. Co., Natrona, Pa., C. K. Williams & Co., Allentown, Pa., S. P. Wetherill & Co., Newcastle, Pa., The Atlantic Dynamite Co., Dover, N. J., Joseph Wharton, Camden, N. J., Charles Lennig & Co., Philadelphia, Pa., the Forest City Manufacturing Co., Ellwood, Ind., and the Stauffer Chemical Co., of San Francisco, Cal. Small shipments of copperas are also made from time to time from Steubenville, O., where it is formed naturally by the oxidation of pyrite.

The price of copperas at New York at the commencement of 1901 was about \$10 per ton against an average of \$14 per ton for the previous year. On account of the advent of new manufacturers in the field during the latter part of 1900, and the consequent increased production in excess of the normal demand, prices declined to \$7 per ton, a figure which ruled the greater part of the year. These quotations are for carload lots, an additional \$1 per ton being asked for lots of smaller size. At \$7 per ton, which includes cooperage and transportation, there is a loss to the manufacturer, and for this reason two or three plants have discontinued operations during the year. The present capacity of the various plants now engaged in the industry is much in excess of the demand and unless some new outlet for the product should be found it will be a problem to dispose of the waste liquors in this form. There is no opportunity for export of copperas for the reason that England, France and Germany also produce it as a by-product in larger quantities and at a lower cost than the United States.

## PROGRESS IN ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY IN 1901.

BY JOHN B. C. KERSHAW.

THE electro-chemical and electro-metallurgical industries have not made such striking progress in the year 1901 as in the two previous years—1899 and 1900; and in some branches the results of overcapitalization and overproduction in the earlier years, have produced the customary evils, and have led to the closing down of plants and compulsory liquidation of the companies that owned them. These evils have been especially manifest in the calcium carbide industry, and the number of factories manufacturing this product at the end of 1901, is probably less than one-third of the number in operation two years ago. New developments, however, are always liable to be unwisely boomed, and it must not be imagined that because the carbide industry has suffered considerably from speculative finance, that the electro-chemical and electro-metallurgical industries generally are in a bad way and liable to gradual extinction.

The details given in the following pages show that 41 distinct products are now manufactured by aid of the electric current, that in the majority of cases the output of these products is increasing, and that a large number of the companies operating these new processes, can show highly satisfactory financial results.

No very noteworthy new processes relating to electro-chemistry or electro-metallurgy have been widely developed in 1901. A new method of preparing bauxite for use in the electrolytic baths for aluminum manufacture, may however cheapen the production of the light metal, and several patents have been granted for electro-metallurgical treatment of zinc ores which may possibly have an important future. Details of a remarkably simple process and apparatus for production of alkalis and chlorine (the "bell" process), have also recently been made public, although this process has been in operation several years in Austria. Full particulars of these patents and processes will be found under their respective headings.

**ALKALIES AND BLEACH.**—No striking progress has occurred in the electrolytic alkali and bleach industry during 1901. The number of works remains stationary at 31, and the power available in these is about 46,000 H.P. The most successful

works appear to be those using the Castner and the Elektron Companies' processes, but even these have ceased for the moment to show any further expansion. It is not yet possible to present any very reliable figures for the total output of the electrolytic alkali works in Europe and America; since in numerous cases the power development is in excess of that utilized for the electrolytic decomposition of salt. Figures for individual works can, however, be given. At the new Middlewich works of the Electrolytic Alkali Co., a 400-H.P. unit of plant was started in April, 1901, and a current of 4,000 amperes and 50 volts was used to work 22 cells of the Hargreaves-Bird type. The plant has since been doubled and in October it was reported that 50 cells were yielding 13 tons of soda crystals and 9 tons of bleaching powder per day. This company, and the Castner-Kellner Co., at Weston Point, use multiple-effect vacuum evaporating pans for concentrating their alkali liquors.

At Bitterfeld, Griesheim, and Rheinfelden, four electrolytic alkali works are operating, and from an official communication, the combined output of these works now equals 25,000 tons caustic potash and 40,000 tons bleach per annum. With these figures before one, it is interesting to note that in 1900, Germany imported 398 tons bleach and exported 25,953 tons of the same commodity. The demand in Germany for bleaching powder is therefore now well covered by the domestic production.

In this connection the following figures showing the proposed changes in the German import tariff for caustic alkali and bleach are of importance:—

*Caustic Alkali.*—Old tariff, 50c. per cwt. New tariff, 42·5c. per cwt.

*Bleaching Powder.*—Old tariff, 36·5c. per cwt. New tariff, 24·5c. per cwt. Though reduced, the duties may still be regarded as prohibitive.

In France the position is somewhat similar, for the domestic production is estimated to amount to 30,000 tons, while the exports in 1900 amounted to 11,300 tons. In both France and Germany therefore, the market for bleaching powder is suffering from overproduction, which retards the development of the electrolytic alkali industry in the two countries. The greater portion of the bleach output in France, is still supplied by the older Le Blanc process, and according to a reliable authority only 5,000 of the 30,000 tons made in 1900, was produced by the electrolytic decomposition of salt.<sup>1</sup> This is particularly noteworthy, for of the five electrolytic alkali works in France, only one, that at Lamotte, appears to be working satisfactorily.

With regard to the profits made by the companies working the various electrolytic processes, the English Castner-Kellner Alkali Co., shows a gross profit of \$314,760 and a net profit of \$216,048 for the year ending March 31, 1901. A dividend of 5% was paid as compared with 8% in 1900, and \$48,000 carried to the reserve. The fall in profits and dividend was attributed to the loss of the South African market for cyanides, and to the high price of fuel and raw materials. The Electrolytic Alkali Co., operating the Hargreaves-Bird process at Middlewich, England, reports a net profit of \$5,956 for four and a half months' work of 36 cells, and considers this a satisfactory result for the start of a new plant. The

<sup>1</sup> *Chemiker Zeitung*, 1901, p. 122.

Chemische Fabrik Griesheim Elektron paid 5% for the year ending December 31, 1900, as compared with 16% for 1899. This firm controls several subsidiary companies and works engaged in the electrolytic alkali industry, and owns an aniline color and picric acid works at Griesheim near Frankfort. A disastrous explosion and fire occurred in the picric acid department on April 25, 1901, and the reduced dividend for 1900 is probably a result of the losses incurred in that disaster, by which 14 men were killed and 100 injured, in addition to enormous destruction of plant and property.

The Electro-Chemical Co., which operated the Richardson and Holland gravity process at St. Helens, England, since 1895, went into liquidation during 1901.

The profits to be obtained in the electrolytic alkali industry depend largely upon the working costs of the process used, and where diaphragms and mercury are dispensed with, these may be reduced to a minimum. The following cost-estimate by Seibert has been published during 1901, and is of interest since it appears to be based on practical knowledge of one of the German secret processes.<sup>2</sup>

ESTIMATE OF COST OF 10,000 KG. 91% CAUSTIC POTASH AND 15,550 KG. 35% BLEACHING POWDER.

| Capital outlay upon plant, 700,000 marks. |        |                           |        |
|-------------------------------------------|--------|---------------------------|--------|
|                                           | Marks. |                           | Marks. |
| Electrical power, 1,050 H.P. gross .....  | 400    | Wages and repairs.....    | 570    |
| Potassium chloride .....                  | 1,922  | Depreciation .....        | 140    |
| Carbon anodes .....                       | 137    | Management.....           | 100    |
| Lime.....                                 | 140    | Interest on capital ..... | 100    |
| Packages.....                             | 374    | Total.....                | 8,948  |

Taking current prices for caustic potash and bleaching powder, this estimate shows the handsome profit of 5,227 marks, or 37% on the capital. The market for caustic potash is, however, a restricted one, though it is well known that the manufacture is a profitable one.

Details of two processes of interest, have been published during the past year—namely, of the Acker "Fusion" process, and of the Aussig "bell" process. Both of these are working upon an industrial scale—the former at Niagara Falls, N. Y., and the latter at Aussig in Austria, and at Bitterfeld and two other places in Germany. The Acker process depends upon the use of molten salt as electrolyte, with a cathode of fused lead. The first patent granted for this use of molten lead was No. 13,568 of 1893, to Vautin, a British inventor. A steam injector is used in the Acker cell to cause circulation of the molten lead cathode, and the decomposition of the alloy of lead and sodium is effected by this steam in a separate vessel. Fig. 1 is a diagrammatic section of the Acker cell. The chief advantages claimed for the process, are high output per unit of plant and reduced charges for fuel, since 98% caustic soda can be obtained in the decomposing vessel. No efficiency figures for this cell have yet been published. The mechanical difficulties that have to be overcome in carrying out this process on a large scale are great and it is yet doubtful whether all of these have been surmounted. In July,

<sup>2</sup> *Elektrochemische Zeitschrift*, November, 1901.

1901, however, Mr. C. E. Acker stated that the process was in successful operation and that solid caustic soda was being produced without any evaporation. The works at Niagara Falls are planned to utilize 2,400 K.W. electrical energy.

The "bell" process is an old one, and has been experimented with at Aussig since early in the nineties. Details of the cell construction are still kept secret, but the broad features of the method are described in English Patent No. 16,129 of 1898. Fig. 2 shows a diagrammatic section of the cell. In this diagram *a* represents the anode, *d* the bell, and *c* the cathodes; while fresh brine is fed into the anode chamber by the pipe *e*, and the chlorine gas escapes by the pipe *g*. The caustic alkali solution leaves the cell by the overflow pipe *f*. The process is a gravity process, no diaphragm being used, and by careful regulation of the respective positions of the anode and cathode and of the flow of brine to the anode compartment in the interior of the bell, it is said to be possible to keep distinct the three layers of electrolyte present in the cell. Owing to the absence of oxygen

FIG. 1.—CROSS SECTION OF THE ACKER ELECTROLYTIC FURNACE FOR ALKALI.

compounds in the anode compartment of the cell, the life of the carbon anodes is enormously increased and ordinary thick lamp carbons are said to last 21 months. The current efficiency is reported to lie between 85 and 90%, and the strength of alkali solution obtained varies between 100 and 150 g. NaOH or KOH per liter. The "bell" process is therefore one of the simplest of the electrolytic alkali processes now in use and the running costs would appear to have been reduced to a minimum. It is noteworthy that careful attention to details of construction and working has turned a process which failed at St. Helens into a success. The process has passed beyond its experimental stage and 24,000 "bells" are now used in the four works named above, a number which will be increased early in 1902. It is believed that the Bitterfeld and Griesheim works are employing this process although official confirmation cannot be obtained. A new patent has just been

ing to the treatment of the mixed potassium hydrate and chloride ined by the "bell" process. The liquors are boiled down to the point commences to crystallize out. Cooled to a temperature lying between °C., this concentrated solution yields crystals of caustic potash con- % KOH, 29.5% H<sub>2</sub>O, and only 0.073% KCl. The latter salt only to crystallize out in quantity when the temperature of the mother unk below 35°C.

sterreichische Verein fuer Chemische Production, which owns the "bell" l the Salzbergwerk Neu Stassfurt, another Austrian company, have ed to work these two patents in Austria, and a considerable increase ian production of electrolytic alkali and bleach may be expected in the

DIAGRAMMATIC SKETCH OF THE "BELL" TYPE OF GRAVITY CELL.

recent communication with the Austrian company controlling the its, an estimate of costs has been taken which, owing to the importance ess, is here reprinted in full. For the sake of comparison with timate given above, all weights and values are expressed in kilograms

ts of a plant consisting of four 600-H.P. generating units, producing 10% caustic potash and 21,600 kg. bleaching powder per day. Outlay 000,000 marks. Working capital, 200,000 marks.

|                                        | Marks.   |                                      | Marks.   |
|----------------------------------------|----------|--------------------------------------|----------|
| Power (1,400 K. W. for 23 hr. per day) | 507.50   | Packages                             | 350.00   |
| Concentrating caustic liquors          | 136.50   | (General expenses (20%))             | 1,038.45 |
| Waste                                  | 3,332.00 | Depreciation (7% on 3,000,000 marks) | 573.65   |
| 400 kg. @ 15.8 M. per 1,000 kg.)       | 211.75   | Interest (5% on 3,200,000 marks)     | 436.90   |
|                                        | 472.50   |                                      |          |
|                                        | 367.50   | Total                                | 7,426.75 |

Taking the prices for caustic potash and bleaching powder previously given in the table referred to earlier in this paper, the value of 14,000 kg. 90% alkali and 21,600 kg. 35% bleaching powder works out to 12,740 marks. This leaves a margin between the actual cost and sales value of the products sufficiently wide to cover all manufacturing contingencies and to leave a satisfactory surplus.

Details of an interesting laboratory investigation by Adolph, using the "bell" type of cell have been published during 1901.<sup>3</sup> The best results were obtained with platinum anodes, the current efficiency under favorable conditions as regards temperature and concentration, rising to 97.68%. With carbon anodes the results though lower were still eminently satisfactory, efficiencies of 92.97 and 92.68% being recorded in two separate experiments. The possibility of working continuously with this form of cell was proved by an experiment lasting seven days, during the last five of which, fresh salt solution was fed continuously into the anode compartment of the cell. The current efficiency obtained during this trial was 82.1%. Adolph closes his paper by urging the technical importance of these results, and he will no doubt be gratified to learn that the "bell" process is already an industrial success and is rapidly extending.

Franke has described during the past year laboratory investigations with a new form of mercury cell in which a falling stream of mercury is used as cathode between carbon and platinum anodes of large superficial area.<sup>4</sup> The advantages claimed for this type of cell compared with the other forms of mercury cell are higher electrical current efficiency and a reduced weight of mercury. In a large scale experiment, a flow of 500 g. of mercury per second sufficed to carry a current of 160 amperes at 4 volts pressure, with carbon anodes, and when platinum was substituted for carbon, a flow of from 100 to 150 g. mercury sufficed to carry the same current. Cells of glazed stoneware only 31.5 in. square, provided with alternative anodes and cathodes, can be utilized to pass currents of 3,000 amperes and 4 volts, so this form of cell certainly economizes space. Owing to the rapid flow of mercury through the cell, the amalgam obtained is not rich in sodium and this, though an advantage from the current efficiency point of view, is a disadvantage when the decomposition of the amalgam has to be considered.

Cohn and Geisenberger have also patented a novel procedure for overcoming some of the difficulties met with in the electrolysis of brine on a commercial scale.<sup>5</sup> The principle of their method is the separation of the alkali hydrate in a solid form at the moment of its formation at the cathode—a result they achieve by working the electrolyzer at a temperature lying between  $-30^{\circ}$  and  $-38^{\circ}\text{C}$ . The form of apparatus required for attaining this low temperature is complicated, and as the expenditure involved would be excessive, in addition to loss of energy efficiency, the method though ingenious can hardly be considered of practical value.

The question of anode material still remains an important one for the electrolytic decomposition of sodium or potassium chloride. The statement of the Aussig Co. that with its "bell" process, when properly worked, ordinary thick

<sup>3</sup> *Zeitschrift fuer Elektrochemie*, May 2, 1901.

<sup>5</sup> *Elektrochemische Zeitschrift*, Sept. 1, 1901; German Patent No. 121,932, of 1900.

mp carbon will last nearly two years, is most remarkable, and shows that the companies using this process must have a great economic advantage over those employing processes that involve frequent renewals of the carbon anodes. The Castner-Kellner Alkali Co. is reported to be using the Acheson graphitized carbons, which are no doubt one of the best forms of artificial carbon for anodes now on the market. Formerly this company prepared carbon for its own use. But even graphitized carbons slowly disintegrate in most forms of electrolytic alkali cell and this consumption and waste of carbon has a further disadvantage besides that of cost. The carbon oxidized at the anode, escapes from the cell as carbon dioxide with the chlorine gas, and its presence leads to difficulties in the production of high strength bleach. To such an extent is this difficulty experienced in some works, that special means have had to be taken in order to free the chlorine gas from carbon dioxide before admitting it to the bleaching powder chambers. Experimental researches carried out by Sproesser with anode carbons in alkali chloride cells during 1901, prove that its waste and disintegration is caused by the presence of oxygen compounds in the electrolyte at or near the surface of the anode, and the life of the carbon anode increases as the formation of these compounds is hindered or suppressed.<sup>6</sup> This result appears to have been satisfactorily achieved only by the Aussig bell cell, which is therefore the most economical as regards cost of anodes in actual use.

Nothing very new has been published on the subject of diaphragms during 1901. Seibert in the article already referred to, states that in the German works using a diaphragm process, it is customary to form diaphragms *in situ* in the cells by the use of a mixture of salt and cement. When this has hardened, the salt is dissolved out and a porous cement diaphragm remains ready for use. Such diaphragms are said to last six months and to possess a longer life than asbestos diaphragms. In this connection it is stated that a curious sickness broke out during 1901 among the men who remove the diaphragms from the cells at the electrolytic alkali works at Lamotte, France. The "Elektron" process is used at this works, and the disengagement and breathing of  $\text{Cl}_2\text{O}$  compounds is believed to be the cause of the trouble. In this respect the "bell" and mercury processes have a common advantage, for neither requires diaphragms in the cell.

As regards the electrical efficiency of the various processes, only few figures have been published during the past year. From authoritative sources it is stated that at the Middlewich works of the Electrolytic Alkali Co., 1,000 watt-hours decompose 1 lb. sodium chloride. The theoretical figure is 2.08 lb. and the energy efficiency of the process therefore works out to 48%, as compared with 54% in the trial runs at Farnworth.<sup>7</sup> The current efficiency with the Aussig bell process is stated to lie between 85 and 90%. As no diaphragm is used, the E.M.F. required by this process must be low and the energy efficiency will therefore work out over 50%. It would be interesting to compare with these figures those obtained by the Acker fusion process at Niagara Falls, but up to the present, no efficiency figures for this process have been published. Efficiency figures for the very similar Hulin fusion process, are given in the article just referred to.

<sup>6</sup> *Zeitschrift fuer Elektrochemie*, November and December, 1901.    <sup>7</sup> *Electrician* (London), March 4, 1898.

Patent litigation in the electrolytic alkali industry during 1901 has been restricted to preliminary legal skirmishes in the British courts relating to the new case, the Commercial Development Corporation vs. the Castner-Kellner Alkali Co. The decision in favor of the former company in the appeal case carried to the House of Lords in 1900,\* did not exhaust the possibilities of the situation, and the Commercial Development Corporation is now taking action against the rival company on the basis of English patents granted to Atkins and Applegarth in the years 1882, 1886, 1888 and 1890. These patents have passed into the possession of the plaintiff company, but the situation has been complicated by a clause in the purchase agreement under which Atkins and Applegarth (the vendors) were to proceed against the Castner-Kellner Co., for infringement. Atkins and Applegarth have not carried out this action, however, and the legal procedure in this new infringement case has consequently got itself into one of those tangles much beloved by the legal profession—on account of the opportunities they afford for a display of legal acumen and for the piling up of handsome fees. The Commercial Development Corporation has at last received permission to proceed in its own name with the action entered for trial in the names of Atkins and Applegarth, and possibly by the end of the year 1902, this case may have progressed through the first stage and be awaiting the inevitable appeal proceedings.

ALUMINUM.—(See the special article on this subject elsewhere in this volume.)

BULLION REFINING.—The electrolytic methods of refining gold and silver are slowly making headway in Europe and America, and refineries of this character now exist in London, Hamburg, Frankfort, Pforzheim, Philadelphia, Perth Amboy, and at one place in France. The Moebius process of refining silver, is in use by Johnson & Sons in London, at Hamburg, and at Perth Amboy, in America. The Gutzkow or Rössler process, is worked at the Frankfort Refinery of the Deutsche Gold und Silber Scheideanstalt, while at Pforzheim, the Dietzel process is employed. The latter process depends upon the use of a solution of copper nitrate in place of the silver nitrate used in the Moebius process. This electrolyte deposits copper at the cathode and dissolves copper and silver at the anode. When the silver in solution has reached a certain degree of concentration, the electrolyte is removed from the vat and the silver is displaced chemically by means of copper filings, or sheet cuttings. Special treatment is required to remove the other impurities, and the acidified solution of copper nitrate is then returned to the depositing vats for electrolysis with new anodes. Using silver-copper alloys as anode material, the value of the recovered copper in some cases is said to cover all the costs of the process.

The Wohlwill process for separating gold-silver alloys, is in use at Hamburg, in France, and in Philadelphia, Pa. The process is covered by the English Patent No. 7,783 of 1896, and is based upon the employment of an acid solution of auric chloride as electrolyte, with anodes of gold-silver alloys, assaying 0.850 fine of gold. A current density of from 1,000 to 2,000 amperes per sq. m. of anode surface is required, with a temperature of from 60° to 70°C.

A refinery for the treatment of gold and silver bullion, is reported to have been

ected by the Deutsche Gold und Silber Scheideanstalt in Sweden, but particulars concerning it are not yet published.

No separate figures for the output of the European refineries can be given for 1901, but in 1900 the Frankfort refinery was reported to have produced 261,312 oz. gold, and 7,186,080 oz. silver. The combined value of the precious metals recovered by the Hamburg and Frankfort refineries in the same year is estimated to have amounted to \$12,000,000.

**CARBORUNDUM.**—The manufacture of this product (silicon-carbide) is carried on under the Acheson patents at Niagara Falls, N. Y., and at several small works in Europe. The latter, however, have mainly been erected to protect the patents in those countries which demand local operation of the protected process, and the Niagara works practically controls the output. In 1901, the production at Niagara Falls amounted to 1,741 metric tons, as compared with 1,089 tons in 1900. Over 2,000 H.P. are now being utilized in the manufacture. During 1901 the carborundum company increased its capital to \$1,000,000. The European works are situated at La Bathie, France; Iserlohn, Germany, and Prague, Austria.

**CHLORATES.**—(See the detailed report on page 326 of this volume.)

**COPPER.**—The appendix to the presidential address delivered by Swan before the Society of Chemical Industry at Glasgow in July, 1901, contained some interesting facts relative to the present position of the electrolytic copper industry in Europe. A circular letter and form had been sent out to the 29 refineries supposed to be operating in Europe, but of these only 11 had replied to the inquiry. The information obtained is reprinted in Table I. below; the letter N in the three

last columns denoting that figures were received, but not for separate publication. The aggregate production of nine refineries in 1900 amounted to 18,962 tons of copper, and Swan estimates that the total European production of electrolytically refined copper is now less than 37,000 tons per annum. Most of the German, Austrian, and Russian refineries are working on a very small scale, and many appear to be dependent upon local mines for their supply of raw copper. As an example of the smallness of some of the European refineries, the annual production at Wittkowitz, Austria, of 180 tons; at Pont-de-Cheruy in France, of 50 tons, and at Besztercebanya, Hungary, of 106 tons, may be noted. The growth of the electrolytic refining industry in America and the practical monopoly of the supplies of copper best suited for the electrolytic process which these refineries enjoy, has hindered further development of the industry in Europe.

The refineries at Swansea and at Pembrey in South Wales, and at Hamburg, all of which formerly had no difficulty in obtaining a sufficient amount of raw copper, are now handicapped by this absorption of American supplies and their output of refined copper has consequently diminished in recent years. Possibly the opening of new mines in Australia and Canada during the last two years will improve the position of European refineries.

The refining companies engaged in the manufacture of copper in tube and sheet form are operating with varying success. The parent English company, working the Elmore process at Hunslet, has changed its name and is now known as the English Metallurgical Co. It has been engaged in the usual litigation with subsidiary companies during 1901 and has paid no dividend to its patient and long-suffering shareholders. The plant at the Hunslet factory near Leeds has been overhauled, and the Secretary stated in December, 1901, that work would be resumed on a large scale in January, 1902. This company has suffered from three evils: overcapitalization, litigation and an incomplete process. The French and German Elmore companies with works at Dives and Schladerm respectively, are more successful; the latter company had a striking exhibit at the Paris (1900) Exposition. The Schladerm works produced 1,200 tons copper, chiefly as tubes, in 1900 and the demand for its product is growing. The French company is still more successful, and 7,000 tons of copper chiefly in tube form, was reported to have been sold in 1900. Its report for the year 1900 showed a gross profit of \$221,000. The raw copper used in this refinery is obtained from Chile and Japan. Both of these foreign companies are said to work a modified form of the original Elmore process and the tubes are drawn down, after deposition. At Schladerm, according to Haber,<sup>9</sup> a current of 250 amperes per sq. m. is used, with an E.M.F. of only 0.70 volts. With regard to the Dumoulin process, in which strips of skin replace the agate burnishers, the directors of the Electrical Copper Co., operating this process at Widnes, Lancashire, have decided to sell the plant and patents. At the fifth annual meeting, held in London on December 27, 1901, it was stated that the failure to earn profits at Widnes had been due to three causes—namely: small output, high price of fuel, and heavy interest on loans. The Widnes works were shut down in July, 1901, and are not to be restarted. As the enormous sum of £405,000 in cash and shares was paid by this company for the Dumoulin patents, overcapitalization might well have been included by the directors as a fourth cause of failure.

The Cowper-Coles centrifugal process, in which the skin friction of the electrolyte supplies the place of agate burnishers and strips of skin, was reported to be about to receive industrial trial in January, 1901, but no details of this trial have yet been published. The Hoepfner extraction process is operated at Papenburg, Germany. The ore is leached with a hot cupric chloride solution, and the iron, nickel, lead, and silver, are separated by a combined chemical and electrolytic treatment. It is reported that ores containing 3.5% Cu are being employed, and that a current efficiency of 90% is being attained with an E.M.F. of 0.80 volt. Although this process was previously tried at Giessen and Wildenau with poor results, better success has attended the Papenburg experiment, and 1 E.H.P.-day

<sup>9</sup> *Zeitschrift fuer Angewandte Chemie*, Feb. 26, 1901.

f 24 hours is said to be yielding 54 kg. copper. The chief difficulty is to prevent the deposited copper from being redissolved in the electrolyte.

A recent United States consular report gives some interesting historical details relating to the Siemens & Halske copper extraction process, in which ferric sulphate was used as leaching agent, a diaphragm being employed to separate the anode and cathode compartments of the cell. The process was patented in 1886 and tried at Geneva in 1890, and at Stolberg about 1893. Both plants failed, probably owing to excessive cost of maintaining the diaphragms. Without diaphragms, the copper cathode dissolved in the ferric sulphate as it re-formed at the anode. It is therefore probable that the history of the Marchese and Siemens & Halske processes may be repeated in that of the Hoepfner copper extraction process, in connection with the working of which, the same difficulty is reported to have arisen.

The growth and progress of the electrolytic refining industry in America, have been dealt with elsewhere in this volume (see p. 218). The disastrous collapse of the "Amalgamated Copper Company's" control of the market and price has also been referred to at length, and its effects on the collateral industries described. The effect of the striking fall in price, upon the new mining companies, floated in London in 1900 and 1901, has however not been specially dealt with. It must be first pointed out, that the collapse has been practically due to the increased production of mines outside the control of the Amalgamated Copper Co. in America, and the Rio Tinto Co. in Europe. The effect of the increased price at which copper was sold in 1899 and 1900 called into existence a large number of new mining companies, having as their object either the re-opening of old mines or the exploitation of new ones. In this connection it may be of interest to give details of the copper mining company flotations in London during 1899 and 1900. The figures are presented in tabular form in Table II.

TABLE II.—NEW COPPER MINING COMPANIES—FLOATED IN LONDON 1899-1900.

That the properties of which these companies gained possession, contained workable copper ores is no doubt true; but estimates of profit based on G. M. B.s selling at £70@£75 per ton, are apt to be falsified when the price has fallen to

£48, and unless the value of copper speedily returns to its former level, the financial prospect for many of these new mining companies will be far from rosy. It is not every copper mining company that is capitalized on the moderate basis of the Rio Tinto Co., which in 1900 paid its ordinary shareholders an 85% dividend. The tendency is for promoters to multiply the maximum estimated profit by ten in order to arrive at a fair (?) capital valuation, and when the maximum profits are based on copper at £74 per ton, the results of this system of finance may prove disastrous for the original investors.

**FERROCHROME AND SIMILAR ALLOYS.**—*Ferrochrome* is being produced by the Willson Aluminum Co. at a new factory on the great Kanawha River, Va. Chrome ores from Asia Minor are used and an alternating current of 3,000 H.P. is employed in smelting these ores in the electric furnace. The ferrochrome produced contains 70% Cr and is used by the Carnegie and Bethlehem Steel companies in the manufacture of armor plates. The same alloy is made at Froges in France by the Société Electro-metallurgique Française; in this case also the electric furnace is used to smelt the ores. At Essen in Germany, ferrochrome alloys are made by the Goldschmidt process, in which powdered aluminum is used as the reducing and heat-producing agent. (See "Aluminum—Utilization," p. 23, this volume.) The ferrochrome alloy containing from 66 to 70% Cr, 30 to 34% Fe and less than 1% C, is said to be the best for use in steel-making as it melts rapidly. Chromium containing 96 to 98% metal made by the Goldschmidt process is not so useful, as it contains from 2 to 4% impurities—chiefly aluminum. The price of 66 to 70% ferrochrome in France is 1,000 fr. per ton, and of pure chromium 7.75 fr. per kg.; but overproduction in this industry is already reported.

*Ferrosilicon* is produced at Meran, by heating in an electric furnace 1,000 parts scrap iron, 410 parts quartz sand and 390 parts coke. The alloy contains 21.5% Si, and costs 200 fr. per ton. The yield is 0.2 kg. per K.W. hour.

*Ferrotitanium* is produced at Niagara Falls by heating scrap iron, titaniferous iron ore and aluminum in the resistance type of furnace; early in 1901, Dunlap reported that 500 lb. were being produced per 24 hours. Ferrotitanium containing 25% Ti and 0.40% C is sold in France at 10 fr. per kg.<sup>10</sup>

*Silicon-copper* is reported to be made by the Cowles Electric Smelting Co. at Lockport, N. J., and is employed as a deoxidizer in foundry work. No details of its manufacture are available for publication.

**HYPOCHLORITES.**—(See report under this title, elsewhere in this volume.)

**IRON AND STEEL.**—The possibility of smelting iron ores in the electric furnace has been proved by the experimental trials of the Stassano process at Rome in 1899 and a plant utilizing 1,500 H.P. has been erected at Darfo in northern Italy for the exploitation of this process on an industrial scale. The company possesses a capital of \$172,000 and it is expected that iron will be produced at a cost of 100 fr. per ton, as compared with 160 fr. per ton by the ordinary smelting methods employed in Italy. The works is designed for an output of 4,000 tons

<sup>10</sup> A detailed description of the manufacture of titanium and its alloys is given in *THE MINERAL INDUSTRY*, Vol. IX., pp. 715-720.

of iron per year and ores from the mines in the Bergamosca Alps will be used. Goldschmidt, after inspecting the smelting furnaces in operation at Darfo on June 19, 1901, has reported favorably on the prospects of this process. Other experimental trials of the electric furnace for the reduction of iron ores have been carried out at Prague in Austria, at Le Praz in France and at the Güssingen foundry in Sweden. The latter works is said to be producing 1,200 kg. steel per day by the Kjellin process and a large installation of smelting furnaces in conjunction with a power station at Dalef is now planned. The erection of an electric smelting works for dealing with the hematite ores of the Bernese Oberland is also projected at Meiringen, in Switzerland; power from the river Aar is to be utilized in this undertaking. Detailed figures for the experimental trials have been published only in the case of the Stassano process, and after submitting these to a close examination,<sup>11</sup> it appears that the electric-furnace methods of iron and steel production can only succeed in localities where coal and coke are abnormally high in cost, and in countries having heavy protective duties on iron and steel.

**LEAD AND ITS COMPOUNDS.**—The Electrical Lead Reduction Co., at Niagara Falls, N. Y., with a capital of \$12,000,000, operates with 600 H.P. Galena is the raw material of the process and is reduced in the electrolytic cells to spongy lead, the sulphur being eliminated as  $H_2S$ . This gas is burned to yield sulphuric acid and the lead is converted into 99% litharge for use in the manufacture of rubber and for accumulators. The present capacity of the works is 10 tons spongy lead per day. The manufacture is reported to be successful, the works have been enlarged after a fire in 1900.

**MISCELLANEOUS PRODUCTS.**—*Ammonium Persulphate* and *Potassium Permanganate* are produced by electrolytic methods at St. Michel, France, by the Société d'Electrochimie. The former salt is much used for bleaching purposes, and in photography.

*Antimony* is being extracted from its ores by an electrolytic method at Banya, Hungary, but it has not been possible to obtain any details of the process used.

**Arsenic.**—The Arsenical Ore Reduction Co. at Newark, N. J., is about to operate the Westman electric furnace method of treating these ores. Rich mispickel from Ontario is to be employed and in the preliminary trials with this ore, 1.27-K.W. hours were said to suffice for smelting 1 ton of ore. All the sulphur in the ore combines with the iron and the arsenic distills over in the gaseous state.

**Artificial Graphite**<sup>12</sup> is produced in increasing quantity in the electric furnace under the Acheson patents by the International Acheson Graphite Co. at Niagara Falls. The method depends upon heating amorphous carbon in presence of ferric oxide, to a very high temperature; the iron is volatilized during the process and the carbon is graphitized. European factories for carrying on the same manufacture exist at La Bathie in France and at Benetek in Hungary. At Chedde and at N. de Briancon in France, graphitized carbon for electrodes is also

<sup>11</sup> *The Electrical Review* (London), June 15, 1900.

<sup>12</sup> Further details of this process are given elsewhere in this volume, under the caption "Graphite."

many, the most important of these being at Essen, where from 50 to 60 tons scrap are treated daily by the Goldschmidt process.<sup>14</sup> During 1901 a company for this purpose was registered in London with a capital of \$48,000 and a plant for the treatment of 50 tons cuttings per month, was to be erected presumably in London. The process to be used was a patented one and was reported to have been tried with success on a commercial scale, but no names or other details were given.

**Wood-Seasoning.**—The use of electrolytic methods in wood seasoning dates from 1898, when the Société Anonyme pour la Senilisation des Bois was registered in Paris with a capital of \$230,000 for operating the Nodon & Bretonneau method. This method is based upon the immersion of half the timber in a tank of liquid, and the use of electrolytic action to drive out the sap and to impregnate the wood with a sodium boro-resinate solution. The timber requires from 5 to 8 hours' treatment in the electrolytic bath and from 3 to 6 weeks for drying. This represents one-sixth of the time at present required. The English rights for this process have been sold to the Electric Timber Seasoning & Preservation Co. registered in 1899 with a capital of \$720,000, and a plant has been installed and operated at Charlton in Kent. Both the French and English companies appear to be overcapitalized and the financial success of this process is somewhat doubtful, excepting when applied to wood required for special purposes.

**NICKEL.**—The chief event in Europe during 1901 in connection with the nickel industry has been the flotation of the Mond Nickel Co. with a capital of \$2,880,000, for purchase of the Mond patents relating to nickel extraction, and for erection of a large works for operating the process at Clydach in Wales. Although the Mond process is not an electrolytic one, this flotation demands notice because it is proposed to work at Clydach on a large scale, and an output is contemplated of from 1,000 to 1,500 tons nickel per annum (equal to one-sixth of the present world production). The Sudbury ore will be used in this works, and several mining properties in that region are included in the purchase price of \$1,560,000, paid to Dr. Mond for the patents and properties, handed over to the new company. The Mond process depends upon the property of carbonic oxide gas to carry off nickel in the gaseous state (as nickel-carbonyl) when passed over the metal in a finely divided metallic state. Full details of the process and plant required for operating it, will be found in the journal named below.<sup>15</sup>

The Hoepfner extraction process is still operated at Papenburg, Germany, by the Allgemeine Elektro-Metallurgischen Gesellschaft. New Caledonian ore is employed as raw material, and a mixed solution of cupric and calcium chlorides is used for leaching. The early decease of Dr. Hoepfner at Denver, Colo., in December, 1900, has removed the inventor of this process at the moment when his guidance and help were most required. Early trials of this process at Wiedenau near Siegen, in 1893 had ended in failure and modifications in the original process had been introduced at Papenburg. In July, 1901, it was reported that this works was producing 1 ton nickel per day.

<sup>14</sup> *Zeitschrift fuer Elektrochemie*, Jan. 9, 1902.

<sup>15</sup> *Proceedings of the Institution of Civil Engineers*, Vol. for 1902.

New deposits of nickel ore are reported to have been discovered in New South Wales and a syndicate of capitalists has been formed to exploit this field. A nickel smelting and refining works is to be established at Newcastle, N. S. W., but it is stated that this works will draw its supplies of ore from New Caledonia. At present the New Caledonian mines are producing 120,000 tons ore per annum, the greater portion of which is shipped to the Tyne and smelted at Glasgow, while the raw nickel is refined at Havre. A movement is on foot to establish smelters in New Caledonia but it is doubtful whether this will succeed, as State aid would be required to compensate for the high cost of fuel.

Le Verrier proposes to extract nickel from nickel ores, by using them as anode material in an electrolyte composed of a 10% solution of nickel, ammonium and sodium chlorides. An occasional addition of sodium hypochlorite is made to oxidize and precipitate the iron, as  $\text{Fe}_2(\text{OH})_6$ , but excess must be avoided. The sulphate salts of nickel and ammonium may also be used in place of the chlorides. The electrolyte must be freely circulated in the bath and it must be withdrawn and filtered at frequent intervals. The bath must be kept neutral or slightly alkaline. A current density of 100 amperes per sq. m. of cathode surface, and an E.M.F. of 2 volts, are found to yield the best results. A higher current density leads to the formation of  $\text{Ni}_3\text{O}_4$  at the cathode. If copper be present, it is deposited with the nickel but a separation can be effected by employing a high current density with an excess of sodium hypochlorite in the electrolyte; nickel and tin are then precipitated as oxides, while the copper is deposited at the cathode. Sulphur in moderate amounts does not interfere with the method as it remains insoluble, and can be removed by filtration. The German patent covering this method is No. 5,781, of 1899. In some respects it resembles the Storer process, although in the latter, the powdered ore was heated with ferric chloride in a closed vessel at  $190^\circ\text{C}$ . for several hours, and the resultant solution was filtered from the  $\text{Fe}_2(\text{OH})_6$ , before electrolysis. As far as it is generally known neither process has yet received industrial trial.

With regard to the electro-deposition of nickel, Pfanhauser has stated that he has worked out a method which permits thick deposits to be obtained in one-twentieth of the time required by the older methods, the deposits being homogeneous, malleable and equal in physical characteristics to plates obtained by smelting and rolling. For articles requiring only a thin coating of nickel, from 2 to 3 minutes in the improved electrolyte bath is said to suffice. No details of the method have however been given.<sup>16</sup> Kugel proposes to obtain thick plates of nickel by using an acid bath at a temperature of  $30^\circ\text{C}$ . or over, the acid being one that is not decomposed by the current.<sup>17</sup>

As regards the use of nickel for the manufacture of nickel steel, Porter has published tests showing that forgings of nickel steel containing from 3 to 3.5% Ni and 0.28% C have a tensile strength 40% higher than steels of the same carbon contents without the nickel. The nickel steels are also less corrodible in salt water. Wilson has published results of physical tests made with nickel-manganese steel containing 25% Ni, 5% Mn and 0.81% C. The specified resist-

<sup>16</sup> *Elektrochemische Zeitschrift*, January, 1901.

<sup>17</sup> English Patent No. 2,994, of 1901.

ance of this steel, is four and a half times greater than that of the German-silver alloy usually employed for resistance coils, and its use is recommended for this purpose. The future of nickel steel in the arts and industries depends largely upon the cheapening of the methods of nickel extraction, and in this connection the new Mond works at Clydach in South Wales and the new extraction works at Sault Ste. Marie in Canada are likely to have important effects upon the industry.

At the Glasgow (1901) Exhibition, the Orford Copper Co. exhibited specimens of electrolytic nickel which analyzed 99.25% Ni. Tests of pure malleable nickel made by this company, showed tensile strengths ranging from 100,000 to 160,000 lb. per sq. in.

**ORGANIC PRODUCTS.**—Details relative to the industrial use of electrolysis in the manufacture of organic products are exceedingly difficult to obtain, for the companies engaged in these manufactures preserve great secrecy as to their methods. A large amount of laboratory work has however been carried out during the last few years and it would seem probable that some of these methods have been adopted for permanent industrial use.

*Iodoform, Chloral, Azo- and Hydrazo-Compounds* have been produced by electrolytic methods and while lacking direct confirmation it is believed that all of these substances are now being manufactured industrially by the new methods. Messrs. Schering of Berlin, the Badische Anilin und Soda Fabrik, Meister Lucius & Brüning, and the Farben-fabrik vorm. Fred Bayer & Co. are the pioneer companies in this field. Perhaps the most direct proof that electrolytic methods are being used is the fact that the Höchst-am-Main color works of Meister Lucius & Brüning are employing 3,000 K.W. continuous current, transmitted to their works by an underground cable from the new generating station. Continuous current is not generally used for motors in Germany, and although a portion of this current is utilized for sodium manufacture (see below), it is unlikely that the whole 3,000 K.W. is employed in this way.

In the United Kingdom, cyanides have been produced by an electric furnace method under the Readman patents, and the inventor stated in 1898, that the patents had been sold to the Scottish Cyanide Co. and that Works were to be built for operating the process at Leven in Fifeshire. Since that date no further details have been made public concerning the company, or its projected Works.

In France electricity is used in the production of heliotropine and vanillin at Courbevoie near Paris. The method is based upon the oxidation of oil of cloves. The Verley ozonizer is employed, and 10,000 kg. of the two compounds are reported to be produced annually. A secondary use of electrolysis in color manufacture is reported from Germany. Chromic acid is one of the most usual oxidizing agents in organic work and the renewal of the spent chromic acid solutions by chemical means is troublesome and expensive. Meister Lucius & Brüning have therefore adopted an electrolytic method for reoxidizing these solutions, which has given very satisfactory results.<sup>18</sup>

**OXYGEN AND HYDROGEN.**—The production of oxygen and hydrogen gases by

<sup>18</sup> *Chemiker-Zeitung*, Oct. 27, 1900.

the electrolysis of water, has become one of the minor branches of electrochemical industry, and works for this manufacture, are now reported to be in operation at Tivoli, Rome, Milan, Zurich, Lucerne, Hanau, Brussels, Toulouse and Montbard. In some cases the gases are used on the spot—(at Rome for inflating military balloons, and at Hanau for melting platinum)—but in the majority of instances the gases are compressed by special pumps and are sold in the usual form of pressure cylinders. Many different forms of decomposing cell have been patented and are in actual use. The majority utilize a solution of sodium hydrate as electrolyte and iron or nickel as the metal for the cell structure and electrodes. In the Schoop apparatus however dilute sulphuric acid is used as electrolyte and the walls of the cell and electrodes are of lead. At Hanau, the Schuckert cell is in use; and a current of 200 amperes and 2.75 volts is employed to decompose the caustic soda solution. Power equal to 60 K.W. per 24 hours is said to produce 100 cu. m. oxygen and 200 cu. m. hydrogen. The daily running expenses of the plant are stated to be \$31.20. At Brussels, the Société l'Oxyhydrique work the Garuti cell and process. In this case also sodium hydrate is the electrolyte, and 12.2-K.W. hours are said to yield 1 cu. m. oxygen and 2 cu. m. hydrogen. The Garuti apparatus is used also at Tivoli near Rome, and at Lucerne. With electric power at 2c. per K.W. hour, the cost of 1 cu. m. oxygen, and 2 cu. m. hydrogen is stated to be only 2.5 cents.

At Oloron Ste. Marie, in the Pyrenees, a similar form of apparatus has been in use since 1898, and 12.5-K.W. hours are required to yield 1 cu. m. oxygen and the corresponding volume of hydrogen. The cost of the H.P. year at this place, is reported to be only \$10.80.

In England, the War Office has established a plant at Aldershot for the production of hydrogen gas—the gas being used for inflating military balloons—and one ampere hour is said to yield 5 l. hydrogen and 2.5 l. of oxygen gas. Both gases are compressed and stored in cylinders until required for use.

In America, electrolytic installations for the production of oxygen and hydrogen gases have been erected in the laboratories of Iowa State College, and of Lehigh University. Caustic soda is used in these cases as electrolyte and cast iron for the electrodes. With current at 2c. per K.W. hour, 1 cu. ft. oxygen gas and 2 cu. ft. hydrogen gas, cost one cent.

OZONE.—There is little to report with regard to new developments in the ozone industry, during 1901. The elaborate exhibit of the Société Industrielle de l'Ozone at the Paris 1900 Exposition has however revived to a certain extent the interest in ozone as an agent for water purification. The exhibit at Paris consisted of a full size working model of the Marmier & Abraham apparatus as used at Lille. Alternating current generated at 2,100 volts was transformed into current at 40,000 volts. The electrodes of the ozonizer were of cast iron cooled by water and were separated by two glass plates 2 m. square, and 7 mm. thick, forming the air channel. The distance separating the glass plates was only 2 mm. The air passed in at the edges of the plates and was drawn away at the center. A special device was required to prevent the current being "earthed" by the water used for cooling the electrodes. The water before treatment with

the ozone is subjected to filtration. The cost of the treatment is stated by the inventors to be 0.0045 fr. per cu. m., or 2.5c. per 1,000 cu. ft. The installation at Lille which was made in 1898, is said to be giving satisfactory results. The Marmier & Abraham apparatus is reported to be in use also at Boleo, in Mexico, but no details of this installation have been published. With regard to the practical operation of this system, Abraham read a paper in November, 1900, before the Société Internationale des Electriciens, in which he emphasized the following points:—

1. 8 to 10 mg. ozone, per liter of air or gas, must be present.
2. The duration of contact between the water and ozonized air, must be sufficient to effect sterilization.
3. The contact must be molecular, for ozone is insoluble in water.

A Gay-Lussac tower packed with flints, is found to fulfil the conditions 2 and 3. This paper is provided with diagrams of the installation at Lille, and readers desiring to consult these, are referred to the volume named below.<sup>19</sup>

Otto has studied the application of ozone to water purification, and has published an interesting memoir upon this subject.<sup>20</sup> He uses in place of the Gay-Lussac absorbing tower packed with flints, a tower filled with trays, and the water and ozonized air are forced into this tower by a cone-shaped injector as spray. The molecular contact between the ozone and the water prescribed by Abraham as necessary to effect purification, would doubtless be more efficiently attained by this apparatus than by a simple flint-packed tower, but no statements have appeared that Otto's form of absorbing-tower has yet received trial upon a large scale. A similar system of mixing the ozonized air with the liquid requiring purification was used in London in 1899, during the trials made with ozone for refining oils and fats, and the principle of the method is undoubtedly right.

Details have recently been published relating to the experimental plant for water sterilization by the Siemens & Halske system erected at Berlin in 1898.<sup>21</sup> This plant was designed to treat 240 cu. m. of water per 24 hours, and comprised ozonizers of the Siemens & Halske type, sterilizing tower, sand filters, and the necessary pumps and storage tanks. Ozonizers of both the plate and tube type have been used and a yield of from 20 to 25 g. ozone per E.H.P. hour with a concentration of 2.5 g. ozone per cu. m. of air are said to have been obtained. The cost per 1,000 cu. ft. of water is 11.8c., of which total, three-fifths represent the cost of electrical energy. This is a much higher cost than that given by Abraham.

The number of bacteriological organisms at Berlin have been reduced from 600,000 to 10 per cu. m. by the combined sand filtration and ozone treatment, water from the river Spree being used in the trials. The capital outlay upon a plant of 3,600 cu. m. per day capacity is estimated to amount to \$32,400, of which \$14,400 represent the plant necessary for an ordinary waterworks and \$18,000 the expenditure upon the electrical and ozone-producing apparatus.

<sup>19</sup> *Bulletin de la Société Internationale des Electriciens*, November, 1900.

<sup>20</sup> *Memoirs de la Société Ingenieur Civil de France*, February, 1900.

<sup>21</sup> *Elektrochemische Zeitschrift*, Nov. 14, 1901.

The water authorities of Moscow are reported to be using ozone for the treatment of their water supply, but no details of this installation beyond the cost, which is said to be \$6.25 per million gallons or 3.9c. per 1,000 cu. ft., are yet forthcoming. One of the London water companies also, is reported to be experimenting in the same direction.

With regard to other uses of ozone, or ozonized air, little progress has been made during 1901. The German firm of Baeyer, in a recent patent, proposes to use ozone for the production of permanganates from manganates, and Siemens & Halske have proposed its use in conjunction with ferric oxide for clearing turbid liquids. At Courbevoie near Paris, 150 to 300 H.P. are employed for generating ozone in connection with the manufacture of organic products, the Verley ozonizer being used.

Chassy has contributed a paper to the French Academie des Sciences on the theory of ozone-production by the electro-static discharge.<sup>22</sup> Experimenting with pure oxygen in place of air and using the Berthelot type of ozonizer, he found that the quantity of ozone produced tends toward a limit determined by the temperature. To obtain a concentration of 7% requires the expenditure of 90 times as much electrical energy as for a concentration of 0.5%. This research therefore indicates that, as in many electrolytic processes, high current and energy efficiency cannot be united with the production of a concentrated form of the compound resulting from the electro-static action. Electro-static discharge not only produces ozone, but also decomposes that already formed and a point is quickly reached where production and decomposition almost balance each other.

**PHOSPHORUS.**—The manufacture of phosphorus by the electro-thermal method has been carried on at Paris, Griesheim, Vernier, Wednesfield near Birmingham, and at Niagara; and these works are believed to be still in operation. Phosphorus manufacturers are however unusually secretive concerning their progress (or the reverse), and nothing can be gleaned from them by direct application. The Readman process (English Patent No. 18,785 of 1895) is used at Birmingham and at Niagara Falls; the Frank & Hilbert process (patented, 1895) at Vernier, and the Billaudot process (patented, 1896) at Paris. The last named process was described by Borchers in *THE MINERAL INDUSTRY*, Vol. VIII., and no further details of it have since been published. The Frank & Hilbert process resembles it, since carbide production is combined with that of phosphorus. As regards the output of phosphorus by the works named above, no reliable figures can be obtained, but it has been estimated that over one-half of the phosphorus production of the world is now manufactured by the electric furnace method. The industry is however somewhat unsettled, owing to the decreasing use of white phosphorus in the manufacture of matches, and the more or less successful attempts to substitute less poisonous substances for it. Thus in France, a match known as the "S. & C." match is manufactured with a non-poisonous composition containing phosphorus sesquisulphide and potassium chlorate. According to Guillet,<sup>23</sup> the world consumption of phosphorus in 1900, amounted to 1,000,000 kg., of which France accounted for 30,000 kg. In 1899,

<sup>22</sup> *Comptes Rendus*, Vol. XX., p. 789.

<sup>23</sup> *Le Genie Civil*, July 14, 1900.

Germany imported 370,000 kg. phosphorus and exported 123,000 kg. Two-thirds of the imported phosphorus came from the United Kingdom. The German consumption is estimated to lie between 200,000 and 250,000 kg. per annum. The only exhibit of German phosphorus at the Paris (1900) Exposition was made by the Griesheim firm "Elektron."

In America beside the company working at Niagara Falls, a company has been formed to operate the extraction process worked out and patented by Dr. Machalske, of Long Island City, N. Y. The process is an electro-metallurgical one and with electric-power, at 3c. per E.H.P. hour the cost of yellow phosphorus is said to amount to only 7c. per lb.

**SODIUM AND SODIUM PEROXIDE.**—The number of factories producing sodium by the electrolytic method has been increased by one during 1900, the unsuccessful electrolytic alkali works at Les Clavaux, France, having been converted into a factory for the production of sodium and its higher oxides. From official information 2,000 H.P. is already being utilized at this place in the manufacture of sodium peroxide and a new compound called "Oxylithe." Castner's process is in use at Les Clavaux. The manufacture is under the control of the Société d'Electrochimie of Paris, which owns the French patents for the Castner process; and also the Gaubert patents for "Oxylithe." The latter is a mixture of sodium peroxide and potassium permanganate produced under pressure. When treated with water, this compound evolves oxygen gas. Important sales are expected for this new substance. A process has also been worked out by Hulin for obtaining pure oxygenated-water from sodium peroxide and it is proposed to use this solution, which contains no soda compounds, in fine bleaching work. Patents have been applied for. Sodium is also reported to be produced in France at Bellegarde, by the Becker process. A fused mixture of sodium hydrate and sodium carbonate is used as electrolyte, and a cone-shaped cover fixed with its lower edges dipping in the electrolyte is kept negatively charged in order to prevent oxidation of the sodium floating on the surface of the molten mass. A current of 1,500 amperes was stated to have been in use at Bellegarde in May, 1900, for the manufacture of sodium and magnesium, but recent confirmation of this statement is lacking.

In Germany, sodium is produced by the Castner process at Rheinfelden, the parent English company, and the Bitterfeld Elektro-Chemische Werke being financially interested in this works. Manufacture was commenced in 1899, but no details of the plant, or its output, are available for publication. The Castner cell and process are operated also at the Farbe-Werke of Meister Lucius & Brüning at Höchst-am-Main, but in this case the sodium produced is used entirely in the color works. The plant, which has been running since 1898, is reported to be of 150 H.P. capacity. The Neuhausen Aluminum Co. also is reported to be producing sodium by an unpatented process, but no details of the process or plant have been published.

In England, the manufacture was originally in the hands of the Aluminum Co. of Oldbury—where the Castner process was developed. This company is now absorbed by the Castner-Kellner Alkali Co. and the manufacture has been

transferred to the large works at Weston Point, near Runcorn. The sum paid for the assets of the Oldbury Company was \$624,000, in shares of the Castner-Kellner Alkali Co. These assets include shares in the Rheinfelden and Niagara sub-companies promoted by the parent concern.

In America, the manufacture of sodium and its peroxide is carried on at Niagara by the Niagara Electro-Chemical Co., 400 H.P. being employed. The Castner cell and process are used and in 1900 the company was reported to be earning large profits. No figures are available for the output of sodium and sodium peroxide for the years 1900-1901. The South African war has temporarily injured the industry, since one of the chief outlets for sodium and its peroxide was in connection with the Rand gold-mining industry. The end of the war is therefore likely to be marked by a considerable increase in the output and profits of the works engaged in this manufacture.

**ZINC.**—The chief event of the past year in the zinc industry in Europe has been the financial collapse of the Smelting Corporation, which was formed to work the Fry process at Ellesmere Port near Manchester. This company was floated with a very large capital in 1898, and smelting works were erected at Ellesmere Port at a cost of \$1,200,000. The zinc was obtained as zinc oxide and it was intended to recover the metal by an electrolytic fusion process but this portion of the process had not been developed when the collapse occurred. The plant was shut down in March, 1901 and the following causes of failure were given:—

(1) Failure of Mr. Fry to meet debenture engagements for \$480,000. (2) Failure of the process to realize the early promises and reports. (3) Increased costs, due to the high price of fuel. (4) Litigation owing to fumes from the cupola furnaces. There is some talk of a reorganization of the company, and negotiations are now being conducted with that end in view.

The Ellerhausen process is another zinc extraction process operating in Europe, in which electrolysis plays only a secondary rôle. In this process, the ore is smelted at a high temperature, and the lead, zinc and silver, are volatilized. The metals are caught, by injecting cold water under pressure into the hot gases at the fans. Sulphides and oxides of lead, zinc, iron, arsenic and antimony are found as sludge, while zinc sulphate is obtained in solution. It has not been stated how the zinc is recovered from this solution but it is possible that electrolysis is employed. The Ellerhausen process is worked at Angoulême in France, by the British Sulphide Smelting Co. and, as the capital of this company is \$3,840,000, it is not improbable that its financial future will be a troubled one.

A distillation process for the treatment of zinc ores, depending upon the use of the electric furnace in place of the usual cupola furnace, has been worked out and patented in Italy by Casaretti & Bertani. Very few details of this process have yet been made public, but it is stated that only 2-E.H.P. hours are required to produce 1 kg. zinc, and that 15 kg. coke are used as reducing agent for 100 kg. ore. The process is said to be worked by the Società Elettrici Metallurgice Lombarda, but official confirmation of this statement is lacking. The Sulphide Corporation of London also has introduced a new type of distillation process into its smelting works in New South Wales. In this case, zinc concentrates

form the raw material, and it is believed that ordinary cupola furnaces are employed. Details of the process however have not been published.

Distillation processes for dealing with complex zinc ores therefore seem to be in the ascendant, and where water power is available and coal scarce, such processes if successful will doubtless be operated in the future with electrical energy.

The Hoepfner process is in use by Brunner Mond & Co. at Winnington, England, and by the Erste Oesterreichische Soda Fabrik at Hruschau, Austria. This process is an electrolytic one and depends upon the use of the waste calcium chloride liquors from the ammonia soda works. A solution of zinc chloride is ultimately obtained which is electrolyzed with carbon anodes in a diaphragm cell. The chlorine obtained at the anode is used for bleach manufacture; and the zinc deposited at the cathode, of 99.95% purity, is sold for special purposes. The process was introduced at Winnington in 1897 and the plant is said to have been increased from its original 400 H.P. capacity, to 1,200 H.P.

The Swinburne-Ashcroft fusion process is about to be tried upon a somewhat extended scale at Weston Point, England, the earlier experimental plant at Milton in Staffordshire, having been dismantled and sold. In June, Ashcroft read a paper before the Institute of Mining and Metallurgy in London,<sup>24</sup> giving the results obtained in the trials at Milton and details of the improvements made in the process since the first patents were applied for. The process as now carried out consists of a cycle of operations, of which sulphur, silver, lead, zinc and chlorine are the final products. The pulverized unroasted ore is mixed with fused zinc chloride in a "converter," and chlorine gas is blown through the mass until all the metals have been converted into chlorides and the sulphur expelled. The fused mass is then decanted from the undecomposed residue and gangue and the silver removed by means of lead. The remaining mixture of fused lead and zinc chlorides is subjected to electrolysis after removal of the lead by the substitution of zinc. The inventors are hopeful of the ultimate success of this process upon which much time and money have been expended in the early trials.

A new electrolytic zinc extraction process invented by Strzoda is also reported to be in operation at Bockenheim, near Frankfort. An electrolyte of zinc sulphate and insoluble anodes are said to be employed, but beyond this details are lacking.

During 1900 and 1901, Lorenz has published the results of important researches bearing on the electrolysis of fused salts.<sup>25</sup> If  $H_2O$  be present, no zinc can be deposited from such fused mixtures, for hydrogen is liberated at the cathode in place of zinc. A treatment with hydrochloric acid, and evaporation, are necessary to remove the last traces of water. The later series of experiments dealt with the phenomena observed when fused lead chloride is the electrolyte.

The only new development to record with regard to electro-galvanizing is the erection of a plant for this work, at Gaarden, Germany, for the firm of Fred. Krupp.

<sup>25</sup> *Zeitschrift fuer Elektrochemie*, Nov. 15, 1900; July 4, 1901.

## FELDSPAR.

THE production of feldspar for the past three years has steadily increased, the output in 1901 amounting to 34,741 long tons, valued at \$220,422, as compared with 29,447 long tons, valued at \$136,773 in 1900 and 26,968 tons (\$137,886) in 1899. Of the product in 1901, 17.3% was ground by the producer, as compared with 84.1% in 1900. The chief sources of supply of feldspar were, as heretofore, Brandywine Summit, Embreeville and Chadds Ford, Pa., Bedford, N. Y., Branchville and South Glastonbury, Conn., Huntington, Mass., and Georgetown and Topsham, Me. The less important mines in Delaware, Virginia and South Carolina yielded a small amount. In 1901, however, Massachusetts reported no output.

For a detailed account of the occurrence, mining and uses of feldspar reference may be made to the article by T. C. Hopkins in THE MINERAL INDUSTRY, Vol. VII.

### PRODUCTION OF FELDSPAR (CRUDE AND GROUND) IN THE UNITED STATES IN 1901.

| State.                          | Crude.      |          | Ground.     |           |

The price of feldspar ranges from \$3 to \$6 per long ton at the mine, according to quality, while the ground product of satisfactory grade brings about \$7 per ton. For pottery uses it must be free from iron oxide, mica and quartz.

The commonest species of feldspar is orthoclase, or potash feldspar, which is the one generally used by potters in the United States. It is the most infusible member of the feldspar group, but thus far very little of the other species has been found in sufficient quantity and purity to mine. The attention of those searching for feldspar is directed to the large quantities of labradorite feldspar rock occurring in the Adirondack region, New York, which often contains very little iron oxide.

## FLUORSPAR.

THE production of fluorspar in the United States continues to be derived chiefly from the mines in Crittendon and Livingston counties, Ky., and Hardin County, Ill., and in 1901 the quantity produced was 19,586 short tons, valued at \$113,803, is compared with 21,656 short tons, valued at \$113,430 in 1900, which indicates a decrease in production of 2,070 short tons, but of only \$373 in value. Of the total production during 1901, 15,886 tons, valued at \$79,783, was crude fluorspar, which was shipped in bulk. The quantity of ground fluorspar sold during the year was 3,700 tons, valued at \$34,100. The statistics, as reported by the various companies engaged in this industry, indicate a larger quantity produced than was shipped, which can only be accounted for by the accumulation of stock at the mines. From other sources, however, it is authoritatively stated that very little stock is carried over at the end of each calendar year, as the season for hauling closes early in the fall and the accumulated stock on hand is rapidly depleted by the demand for the winter trade.

With the exception of the output from Rosiclair, Ill., and a comparatively insignificant quantity mined on the Kentucky side of the Ohio river, near the mouth of the Cumberland river, all of the fluorspar mined in the district mentioned above is shipped by the Illinois Central Railroad. The producers of fluorite were the Kentucky Fluor Spar Co., the Fluorspar Co., Western Kentucky Mining Co., and Chicago Mining Co., all of Marion, Ky.; the Eagle Fluorspar Co., at Salem, Ky., and the Rosiclair Lead & Fluorspar Mines at Rosiclair, Ill. Early in 1902 the Kentucky Fluor Spar Co., which has been the chief producer of fluorspar in recent years, absorbed The Fluorspar Co., and is now by far the largest producer in Kentucky. This company and the Rosiclair Lead & Fluorspar Mines produced nearly 80% of the total output during 1901.

A deposit of fluorspar has been reported in Yuma County, Ariz., containing veins from a few inches to 7 ft. or more in width. The crystals are of beautiful, characteristic colors—blue, green, red and purple—and should the demand for the use of fluorspar in smelting operations be greatly increased a market will be created for the Arizona mineral. Deposits of fluorspar have also been reported in Smith, Towsdale and Wilson counties, Tenn., and the Tennessee Fluorite & Mining Co. has been incorporated to work deposits near Bellwood, Smith County, Tenn. The deposits of fluorspar in Illinois and Kentucky are worked by shafts and drifts. The crude material is removed from the mine and generally concentrated by hand cobbing, machine or by water jigs, in some instances the product is shipped directly after washing, as it comes from the mine. It is interesting to note that valuable by-products are being saved. In addition to the fluorspar output the Rosiclair Lead & Fluorspar mines produce galena, and the Chicago Mining Co., Kentucky Fluor Spar Co., and Western Fluorspar Co. produce zinc carbonate.

## PRODUCTION OF FLUORSPAR IN THE UNITED STATES. (IN SHORT TONS.)

| Year.    | Tons. | Value.   | Per Ton | Year.    | Tons. | Value.   | Per Ton | Year.    | Tons.  | Value.   | Per Ton |
|----------|-------|----------|---------|----------|-------|----------|---------|----------|--------|----------|---------|
| 1890.... | 8,250 | \$55,328 | \$6.70  | 1894.... | 6,400 | \$38,400 | \$6.00  | 1898.... | 12,145 | \$93,935 | \$7.73  |
| 1891.... | 6,390 | 38,000   | 6.00    | 1895.... | 4,000 | 24,000   | 6.00    | 1899.... | 24,080 | 152,055  | 6.35    |
| 1892.... | 9,000 | 54,000   | 6.00    | 1896.... | 6,000 | 48,000   | 8.00    | 1900.... | 21,856 | 113,430  | 5.24    |
| 1893.... | 9,700 | 63,050   | 6.50    | 1897.... | 4,379 | 36,364   | 7.65    | 1901.... | 19,586 | 113,908  | 5.81    |

For the American market fluorspar is divided into six grades, namely, American lump No. 1, American lump No. 2, gravel, crushed, ground fine, and ground extra fine. The foreign product appears in two grades only—lump and fine.

The prices for fluorspar per short ton during 1901 did not change materially from the quotations existing in 1900, viz.: Gravel spar, \$5.26; lump spar, \$5.50; and ground spar, \$10, f. o. b. at mines. The average value of the fluorspar produced during 1901 was \$5.81, as compared with \$5.24 in 1900.

The imports of fluorspar into the United States are not separately classified by the Bureau of Statistics of the Treasury Department, the quantity imported being included among minerals and ores not elsewhere specified.

The quantity of fluorspar produced is mainly consumed in the open-hearth furnaces for the manufacture of steel and in foundry cupolas for melting pig iron; smaller quantities are used in the manufacture of opalescent glass and in the preparation of hydrofluoric acid. It is claimed that fluorspar can be used to advantage in copper and nickel smelting, particularly for the removal of silicon and arsenic during the refining of copper.

## PRODUCTION OF FLUORSPAR IN THE PRINCIPAL COUNTRIES. (IN METRIC TONS.)

| Year.     | France. | Germany. |          |          |         |              | Spain. | United Kingdom. | United States. | Total. |

| 1900..... | 3,430   | 6,028    | 7,456    | 13,820   | 2,019   | 987          | 4      | 1,472           | 19,646         | 54,392 |

From the official reports of the respective countries except the United States, for which the totals are based on direct returns of the producers, and for Anhalt, Saxe-Weimar and Schwarzburg-Sonderhausen, which are due to the courtesy of Herr von Scheel, director des Kaiserlichen Statistischen Amts. (a) Includes 557 metric tons from Weimar

## COMMERCIAL HYDROFLUORIC ACID.

BY KARL F. STAHL.

HYDROFLUORIC acid is made by decomposing ground fluorspar with sulphuric acid in cast-iron vessels and absorbing the resulting fumes of hydrofluoric acid in leaden vessels containing more or less water, according to the strength desired. The commercial acid, containing from 30 to 60% HF, is stored and shipped in lead vessels or gutta percha bottles. Weaker acid of about 35% and less can be stored for a limited time in wood and is sometimes shipped in whiskey barrels. The so-called "chemically pure" acid is packed, in this country, in ceresine bottles, which must be kept away from the Bunsen burner, as the melting point of the ceresine is low. In Europe the c. p. acid is shipped, either in gutta percha or platinum bottles, but in course of time the acid takes up

mineral and organic matter from the gutta percha and ceases to be c. p.—platinum bottles are the best, but require a heavy first outlay.

*Impurities.*—Among the unavoidable impurities always present is hydrofluosilicic acid, which is the most important because the fluorine combined with silica is perfectly useless. The source of hydrofluosilicic acid is free or combined silica in the fluorspar. American ground fluorspar containing less than 1% silica may now be purchased; samples of English spar contain about 3%, while 6 samples of German spar contained from 0.1 to 0.7% silica. The following method for the determination of silica in fluorspar is not accurate, but gives an idea of the quality: 1 g. of ground fluorspar, in a platinum dish with a small platinum spatula, is dried at about 130°C., weighed exactly, moistened with hydrofluoric acid, stirred with spatula, evaporated to dryness on the water bath; this is repeated, then dried again at 130°C. and weighed. The difference is assumed to be silica, which is only correct when free silica is present. For every part of silica in the spar about 4 parts of fluorspar and 5 parts of sulphuric acid are wasted, or for every percentage of silica at least 10% (4% for spar and about 6% for sulphuric acid) should be deducted from the value of the spar.

Sulphuric acid, which is distilled over in small quantities from the decomposing vessel, does not harm hydrofluoric acid for use in etching glass or pickling iron; but must be determined in the analysis, otherwise it would be figured as hydrofluoric acid. On evaporation and calcining, commercial acid should leave but a trace of non-volatile matter. The commercial acid of to-day usually contains from 1 to 1.5%  $\text{SiF}(\text{HF})_2$ , and from 1 to 2%  $\text{H}_2\text{SO}_4$  only as impurities, and is purified for analytical purposes by distillation in platinum vessels and by the use of c. p. sulphuric acid.

The following method is used for testing: The sample is placed in water of 15°C. for at least 5 minutes, and the sp. gr. is taken. Then with the aid of a small platinum tube, serving as a pipette, three portions are weighed out: (A) 2 g. in a 5-c.c. platinum crucible; (B) 2 g. in a 40-c.c. platinum crucible; (C) 4 g. in a small platinum dish.

A. Place the small platinum crucible, covered with its lid, in a large platinum dish, holding about 100 c.c.; then run, according to the expected percentage, 25 or 50 c.c. normal caustic solution (40 g. NaOH per liter) from a pipette into the dish, upset the covered crucible and mix the acid and alkali with a platinum stirrer, add 2 drops of a solution of phenolphthalein (1 g. in 100 c.c. alcohol) and then more of the normal soda solution from a burette till the colorless liquid assumes the characteristic bright red, which an alkali imparts to phenolphthalein. Heat to about 50°C.; the red color will disappear again; finally add normal solution from the burette slowly till the red color remains, even if heated again, which indicates that all free sulphuric acid, hydrofluoric acid and hydrofluosilicic acid has been neutralized. The number of c.c. used we call "a." If litmus is used in place of phenolphthalein, the soda solution has to be added till the color is perfectly blue, but the end of the reaction is indistinct, while with phenolphthalein it is very sharp.

B. To the acid in the large platinum crucible (2 g.) add 5 c.c. water (meas-

ured approximately), then slowly about 2 g.<sup>1</sup> K<sub>2</sub>CO<sub>3</sub>, either in small pieces or in concentrated solution; add about 15 c.c. of 50% alcohol and then about 5 c.c. 95% alcohol, which will bring the whole to a volume of about 25 c.c., containing about 50% alcohol;<sup>2</sup> let it stand for at least 1 hour. Filter<sup>3</sup> and wash the gelatinous precipitate, consisting of potassium silicofluoride, with 50% alcohol till blue litmus paper ceases to be turned red by the filtrate. Throw the filter with the precipitate into a platinum dish, add about 25 c.c. water and warm to about 50°C.; titrate slowly with normal caustic soda solution and phenolphthalein, as described in the determination of total acidity. The number of c.c. used we will call "b."

C. Place the platinum dish containing 4 g. of the acid to be tested on a water-bath under a hood and evaporate till acid fumes have completely ceased. Titrate the remaining syrupy liquid (which contains the free H<sub>2</sub>SO<sub>4</sub>), cold with normal soda solution, using either litmus or phenolphthalein as indicator. The number of c.c. used we will call "c."

The number of c.c. of normal soda solution used in the first titration and called "a" represent the alkali necessary to neutralize the hydrofluoric, hydrofluosilic and sulphuric acids, and to find the number of c.c. used for hydrofluoric acid alone, subtract those used for hydrofluosilic and sulphuric acids. Having employed 4 g. of substance for the determination of the H<sub>2</sub>SO<sub>4</sub>, the number of c.c. used for that determination must be divided by 2. The number of c.c. used for HF alone equals  $a - (\frac{3}{2}b + \frac{c}{2})$ , and as each c.c. normal solution indicates 0.020 g. HF and 2 g. of substance have been used, the number of c.c. found by the above formula express the percentage of free HF, therefore  $a - (\frac{3}{2}b + \frac{c}{2}) = \text{percentage free HF}$ . From the foregoing the calculation of the percentage of SiF<sub>4</sub> (HF)<sub>2</sub> is an easy matter. 1 c.c. normal NaOH indicates 0.055 SiF<sub>4</sub>(HF)<sub>2</sub>, which was obtained from 0.036 SiF<sub>4</sub>(HF)<sub>2</sub>. Having used 2 g. of substance, 0.036 must be divided by 2 and multiplied by 100 to get the percentage, or,  $b \times 1.8 = \text{percentage SiF}_4(\text{HF})_2$ . The percentage of free H<sub>2</sub>SO<sub>4</sub> is obtained by multiplying (c) the number of c.c. used with 0.048, dividing by 4 and multiplying with 100, or,  $c \times 1.2 = \text{percentage free H}_2\text{SO}_4$ . Other free acids, muriatic or nitric, which would influence the accuracy of the determination, are not likely to occur in commercial hydrofluoric acid and their presence can easily be detected by well-known analytical methods.

<sup>1</sup> The amount of K<sub>2</sub>CO<sub>3</sub> is calculated to neutralize the acids only partly. To avoid an excess it is advisable to test the liquid with litmus paper, which should show a strong acid reaction. But there should be at least enough potash to form SiF<sub>4</sub>(KF)<sub>2</sub> with the SiF<sub>4</sub>(HF)<sub>2</sub>. In analyzing acid of entirely unknown composition, 1.06 g. K<sub>2</sub>CO<sub>3</sub> is taken for every 1 c.c. normal soda solution used for the determination of total acidity. Potassium chloride might be used in place of the carbonate, but in that case free HCl is formed, in which the silicofluoride of potassium is somewhat soluble.

<sup>2</sup> If the liquid contains more than 50% alcohol, fluoride of potassium is precipitated; if much less alcohol, silicofluoride of potassium may remain in solution.

<sup>3</sup> A platinum funnel is used, because glass funnels are acted on, but that does not influence the accuracy of the method.

## FULLERS EARTH.

THE production of fullers earth in the United States during 1901 was 14,112 short tons, valued at \$96,835, as compared with 11,813 short tons, valued at \$70,565 in 1900, and 13,620 short tons, valued at \$81,900 in 1899. The greater part of the product continues to be supplied from the mines at Quincy, Fla., the balance being obtained from the mines in Arkansas, California, Colorado, and New York.

*Imports.*—The imports of fullers earth in 1901 were 2,918 long tons of lump earth, valued at \$17,230, and 7,851 long tons of ground earth, valued at \$63,467 (total: 10,769 long tons, valued at \$80,697), as compared with 2,431 long tons of lump earth, valued at \$14,750 and 5,742 long tons of ground earth, valued at \$50,047 (total: 8,173 long tons, valued at \$64,797) in 1900. Under the present tariff the duty is \$1.50 per ton on lump earth and \$3 per ton on ground earth.

*New York Market.*—Demand for fullers earth was greatest in the spring and summer months of 1901 for use principally in filtering and clarifying oils. Large imports of English earth, chiefly powdered, sold at steady prices. The bulk of the domestic production is generally contracted for ahead, hence quotations remain practically unchanged throughout the year. Prices for ordinary lump during 1901 were 75c. per 100 lb.; refined lump, \$1.25 per 100 lb., and powdered, 85c. per 100 lb.

*Uses.*—The chief uses of fullers earth is in fulling wool and in deodorizing and clarifying fats, oils and greases. Refiners of lard, cottolene and allied products are important consumers. Chief among these are N. K. Fairbanks Co., Swift & Co., Armour & Co., Nelson Morris & Co., Cudahy Packing Co., and G. H. Hammond & Co.

Tests of fullers earth from Bakersfield, Cal., have proven it to be equal to the English earth, and it is stated that contracts were closed with Missouri river packers and other consumers which increased the shipment for 1901 to 2,500 tons, a very considerable increase over the shipments in the previous year. The analysis of the Bakersfield fullers earth is as follows:  $\text{SiO}_2$  54.32%,  $\text{Al}_2\text{O}_3$  18.88%,  $\text{Fe}_2\text{O}_3$  6.50%,  $\text{CaO}$  1.00%,  $\text{MgO}$  3.22%, ignition loss 11.86%, alkali (by difference) 4.21%. A comparative test of Bakersfield fullers earth with imported English fullers earth showed that 10 lb. of the former equalled in bleaching strength 9.75 lb. of the latter. The tests were made on cotton-seed oil with 5 and 10% quantities of earth at a temperature of 100°C. for 45 minutes. The English earth used analyzed:  $\text{SiO}_2$  54.20%,  $\text{Al}_2\text{O}_3$  14.30%,  $\text{Fe}_2\text{O}_3$  6.30%,  $\text{CaO}$  1.25%,  $\text{MgO}$  2.72%, ignition loss 17.44%, alkali (by difference) 3.79%.

## GARNET.

THE production of garnet for abrasive purposes in the United States during 1901 amounted to 4,444 short tons, valued at \$158,100, as compared with 3,285 short tons, valued at \$92,801 in 1900. The output was derived mainly from the mines in the vicinity of Ticonderoga, N. Y., which furnished 2,500 short tons, valued at \$70,625 during 1901, as compared with 2,508 short tons in the preceding year. The balance of the total production in the United States was obtained from Chelsea, Pa., Roxbury, Conn., and from North Carolina. The last-named State entered the list of reporting producers in 1899, and has contributed a product of high grade. The price for garnets remained unchanged throughout the year, although the demand was slightly increased owing to the generally prosperous condition of the country and to the stocking up of a large concern which has recently entered the garnet paper trade. No new mines have been opened in the Ticonderoga region during the year.

The geology and mineralogical character of the Adirondack deposits and the preparation and uses of the mineral product are given in THE MINERAL INDUSTRY, Volume VI.

## GEMS AND PRECIOUS STONES.

THE progress of the gem and precious stone industries in the United States during 1901 was mainly in the great activity displayed in the turquoise mines of New Mexico and in the emerald-beryl mines of North Carolina, owing to the increased use of the matrix as well as the gems for jewelry. The sapphire mines of Fergus County, Mont., also were actively developed by two mining companies. **DIAMONDS.—United States.**—The diamond deposits in the United States were fully described by William H. Hobbs, *THE MINERAL INDUSTRY*, Vol. IX., 1900, p. 301. The production in diamonds for the year 1901, for the United States amounted to but \$100 in value. The only new discovery of diamonds of interest in 1901 was the finding of a solitary gem in Lee County, Ga., the first ever found in that region.

**Africa.**—The report of the De Beers Consolidated Mines, Ltd., for the fiscal year ending June 30, 1901, shows that diamonds to the value of £4,628,845 were sold by the company during the year. After deducting expenditures of £2,194,207, the profit balance for the year was £2,434,639, from which dividends to the amount of £1,579,582 were paid. The average yield per load of blue ground and dumps from the De Beers and Kimberley mines for the fiscal year was 0.76 carats, at an average value per carat of 39s. 7d. The average yield per load for the Premier mine, at Wesselson, was 0.295 carats valued at 27s. 4d. each. During the year the De Beers Co. purchased the claims of Mr. Leopold Herz in the Dutoitspan mine for £12,000; this mine now belongs wholly to the De Beers Co., except for the claims owned by the Griqualand West Diamond Mining Co., which are leased to the De Beers. A new contract for the sale of the diamonds has been entered into which gives the De Beers Co. a share in the profits of sale, as well as a higher price than formerly for the diamonds. During the latter part of the year the capital stock of the company was changed from £3,950,000, divided into £5 shares, to an issue of £4,500,000 divided into 800,000 shares of preferred stock at £2 10s. par value, and 1,000,000 shares of common stock of the same par value. The preferred stock will be entitled to dividends of 40% annually. Ten thousand preferred shares are held in the treasury and the life governors accept 160,000 shares to cancel their rights which entitled them to 25% of all profits made in excess of 36% on the stock. It is reported that negotiations for the purchase by the De Beers Co. of the Jagersfontein mine were completed in 1901. American

electrical machinery to the amount of \$135,000 was ordered, which included two Westinghouse-Parsons steam turbines of 1,000 kw. each, two 1,000 kw. direct-connected alternating current generators, all to be built by the Westinghouse Electric & Manufacturing Co., of Pittsburg, Pa. In the early part of the year a canary-colored diamond weighing in the rough 600 carats was found. As cut in 64 facets it weighs 207.75 carats, is absolutely flawless and has a very brilliant luster. It was exhibited at the Pan-American Exposition at Buffalo, in 1901.

The Orange Free State & Transvaal Diamond Mines, Ltd., capitalized at £550,000 in £1 shares, owns, in the Orange River Colony, approximately 12,000 acres, comprising the Kaal Vallai and Dirksburg freehold farms. The company also has leases of diamondiferous land east of Pretoria in the Transvaal. The company's machinery is capable of handling 5,000 loads of clay per day, and 250,000 tons of blue clay have been weathering on the floors during the Boer war. The Lace Diamond Mining Co., Ltd., capitalized at £250,000 in £1 shares, discovered diamonds on its property of 5,000 acres in 1898. From February to October, 1899, 47,017 loads of yellow ground were washed for a yield of 9,888.5 carats, or 21.03 carats per 100 loads. Before the war machinery capable of treating 1,000 loads per day of 12 hours was erected, and a duplicate of this plant is expected to be in operation by July, 1902. It is estimated that the company has three years of work in the yellow ground in sight before reaching the bed of blue clay known to exist in the lower levels of the property.

*Australasia.*—The estimated production of diamonds for the year 1901 is valued at £9,756. The diamond output for New South Wales was much restricted in 1900 owing to the extended and protracted drought. The production being but 9,828.5 carats valued at £5,663 against 25,874 carats valued at £10,349 for 1899. The mines of the Inverell Diamond Field Co., Ltd., at Copeton (formerly Boggy Camp) were closed during the greater part of the year pending a reconstruction of the company. The quantity of wash dirt treated during the year was 4,275 loads for a yield of 3,546.5 carats of diamonds, valued at £1,063. The Soldiers Hill Diamond & Tin Mining Co. recovered, from May, 1899, to December, 1900, diamonds to the weight of 5,887.5 carats valued at £4,256. The Elliot Diamond & Tin Mining Co. during 1900 treated 140 loads of wash for a yield of 637 carats of diamonds and one short ton of tin. Operations were commenced November 1, 1900. The diamonds average 3 or 4 to the carat and have been sold locally for 16s. per carat. During 1900 the Australian Diamond Fields Co., of Copeton, treated 422 loads of wash for a yield of 466 carats of diamonds valued at £350. The Malacca mine treated 70 loads of wash for a yield of 202.5 carats of diamonds valued at £160. Other small holdings of the Copeton field produced 2,400 carats of diamonds valued at £1,583. The Bingara mining division produced almost nothing during the year owing to the great scarcity of water, the nearest stream being four miles away. Diamonds are reported at Watson's creek, in the Bendemeer division and at Beryl, on the Cudgegong river, in the Mudgee mining district. At Nullagine, in West Australia, 230 tons of conglomerate were treated for a yield of 25 small diamonds valued at £24, and 77.7 oz. of gold.

*South America.*—The principal diamond mining States of Brazil are Bahia

and Minas Geraes. The districts of Diamantina, Jequitinhonha, Abaithe, Bagagem, and Saccado Veados, in Minas Geraes are the principal regions where mining is carried on. Diamantina is divided into the localities of Sopa, Boa Vista, Curalinho, and Lavras, the latter the richest diamond deposit in all Brazil. In the State of Bahia the most prominent districts are Sincova, Cannavieiras, and Salobro. The last-named district was supposedly exhausted in 1891, but recent investigations may lead to a revival of diamond mining there. The workings in this district were confined to the beds of the streams and shallow holes on the benches. The diamonds occurred in the naturally concentrated gravel beds, in pockets, with no regular system of occurrence. The lower diamondiferous strata was not explored owing to the limited resources of the miners and the frequent and disastrous floods. The exports of precious stones for the first seven months of 1901 from the State of Minas Geraes amounted to almost \$250,000 in value.

*British Guiana.*—During 1901 a large number of prospectors and mining companies were operating in the Mazaruni diamond fields. The route to the fields follows the coast for 20 miles from Georgetown, thence 50 miles up the Essequibo river to Bartica, from there to San-San-Kopai Landing about 1.5 miles above Putareng creek on the left bank of the Mazaruni river. Navigation is difficult on account of the numerous rapids and cataracts, and prospecting expeditions are costly to outfit. The expense of outfitting for three months for an expedition of eight men and transporting them from Georgetown to the diamond fields is \$1,000. The principal diamond diggings are five miles back from the Mazaruni river. Among the prominent companies operating in the district are: The British Guiana Diamond Syndicate; the Fogel-Armeny Syndicate, at Saranamoo; the Stripp, Menzies, and Morris Syndicate, on Jasper creek; the Marshall Syndicate; the Nascimento Syndicate; the Wieting Syndicate, between Putareng and Saranamoo creeks; the Barnard Syndicate, on Saranamoo creek; the Forbes Syndicate; the Ho-a-Hing Kenswall Syndicate; the Harrison-Richter Syndicate; and the Biallostowski Syndicate, on Putareng creek. Some of the larger syndicates have their own boats plying between the diamond fields and Georgetown. The production of diamonds for the first three months of 1902 was 3,426.5 carats, valued at \$41,062 in contrast with a production for the same period of 1901 of 326 carats valued at \$4,656.

*Dutch East Indies.*—Diamonds are found in Dutch Borneo near the sources and along the courses of the Martapoera, Riam Kiwa, Riam Kanan, and Bandjoe Irang rivers. The Bandjoe Irang field, formerly the most important, together with the region of Tjampaka, is worked out. All the fields are in the southeastern portion of Borneo, and still produce stones in small quantity but of good quality.

*India.*—In 1900 Central India produced 169 carats of diamonds valued at \$350.

**EMERALDS.**—Emeralds are mined in Mitchell County, N. C., and in Blackburg, S. C. The emeralds from Mitchell County are cut in the matrix, polished, and sold in quantities.

The Muzo and Coscuez emerald mine in Colombia is the only one in the world which is worked continuously. The mine is very crudely worked, but the emeralds are of fine color and excellent quality. The mine is located 50 miles from

Bogota, very near the route of the Inter-Continental railway. The Government of Colombia leases the mines to an English syndicate, which has made millions from its profits of operation.

The firm of Streeter & Co., of London, has a concession from the Egyptian Government to prospect for emeralds in the region of the Red Sea coast until 1904. In the winter of 1899-1900 an expedition was sent out by Streeter & Co. to explore the ancient emerald mines of Jebel Zabara, about 80 miles south of Um Rus, and 25 miles from the harbor of Sherm Sheik, on the Red Sea. In ancient times the emeralds of Zabara were noted for their fine quality and the large quantity produced. The emeralds occur in a matrix of mica schist together with large quantities of beryl. The zone of schist extends from beneath the Nubian sandstone to the westward of Jebel Nikhari, south of the Hamesh gold mines, and thence eastward to Jebel Zabara and the sea. Another zone of micaceous and talcose rock in which emeralds might be discovered lies to the north of Eridia, eastward of Kenah.

A discovery of emeralds is reported during the latter part of 1901, in the vicinity of Corocoro, Bolivia.

Emeralds are found in the Balkan Mountains, Russia, but the annual output is small and the finds are irregular.

**OPAL.**—Mining for opals in New South Wales is confined to White Cliffs, in the Wilcannia district, the search being limited to shallow depths. From September, 1899, there has been a steady decline in the population of White Cliffs, the estimate for August, 1899, being 2,500, while December, 1900, showed but 1,400 persons, due to the overproduction of the poorer quality of opals and the consequent restriction of mining operations. In 1900 a comparative scarcity of first-class opals was reported, buyers being unable to purchase as much as desired. During 1900 the White Cliffs Opal-Mining Co., Ltd., had 400 tributors working on the company's leases. The estimate of the value of the output of 1900 is £80,000. The declared value of the parcels weighing about 51,260 Troy oz. consigned through the postoffice was £44,417, with no estimate for amounts forwarded by coach or taken personally. The value of the production of opals for the year 1901 for the White Cliffs field is estimated at £120,000 an increase over 1900 of £40,000, which is due to the large number of men attracted to the field by the depression in the Broken Hill and Cobar mining divisions.

The principal opal mining district in Mexico is in the State of Queretaro, near La Esperanza, where large quantities are produced and cut annually of the noble opal, fire opal, harlequin, and lechosos (the latter showing red and deep-green flashes of color). The State of Hidalgo produces from Zimapan valuable quantities of the fire opal annually. At Huitzuco and San Nicolas del Oro, in the State of Guerrero the opals are transparent and streaked with red, green and blue. Opals valued at about \$10,000 are said to be exported annually by one mine owner from this State. Large quantities of noble opals are mined in Central America, and opals are also mined in Arizona and New Mexico, U. S. A.

**RUBY.**—The report of the Burma Ruby Mines, Ltd., for the fiscal year ending February 28, 1901, shows total receipts including rubies sold, interest, etc., amounting to £110,626; the expenses amounted to £70,781, leaving a net

balance of £39,845. Deducting the percentage payable to the Government of India for rental, amounting to £12,440, there remained a net profit of £27,405, which, including the balance brought forward from the previous fiscal year, yielded a sum available for distribution of £36,286. The directors recommended a dividend of 17·5% equal to £26,162, and carried forward £10,124. During the fiscal year 947,444 loads of ruby earth were washed at an average cost of 10·29d. per load, against 888,135 loads at 10·39d. for the previous fiscal year. The erection of a two-pan washing machine at Padansho, near Kyouklongyi, was completed, enabling the output for this mine to be doubled, and the surface stripping for the opening of the new mine at Choungzone was begun. A third electric installation for the working of this mine was received at Mogok. The Burma rubies occur in beds of coarse gravel mixed with graphite, garnet, and spinel. The Burma rubies more nearly approach the pigeon-blood color than those found elsewhere, and consequently the output is more valuable proportionately. The New Kabue Gold Mines of Siam, Ltd., although inactive in the gold field during 1900, took over the lease of the sapphire and ruby mines at Pailin. The company does not engage directly in mining but grants licenses to native diggers, and leases out the various surface rights. Bo Wen and Taphan Hin, in the Province of Chantaboon, Siam, yield the greatest output of rubies, although the Bo Yan and Navong mines, in the Province of Krat, produce large quantities annually. The Siamese rubies are much darker in color than the Burmese ones and have a tendency toward a purplish color. Occasionally the famous pigeon-blood rubies are found in the valleys and water-courses surrounding Ratnapura and Rakwena, Ceylon. While the Ceylon rubies are limpid in brilliancy and pale in color, they are not so valuable as Burmese or Siamese rubies. The total production of rubies for 1900 in India amounted to 214,856 carats. A ruby worth when cut barely £1 was found in 1900, at Beatrice creek, in the Jordan creek gold fields, Queensland, Australasia.

**SAPPHIRES.**—Sapphires of high quality and variegated colors and tints are found at Rock creek, in Missoula County, Mont.; on the Missouri river, between Cañon Ferry and American Bar the sapphires are bluish-green, blue, and white, and are mined in large quantities; in Deer Lodge County, on Cottonwood creek, sapphires of variegated colors are found, and at Yogo, in Fergus County, are the mines operated by the American Gem Mining Co. and the New Mines Sapphire Syndicate, of London, which last produced in 1901 about 100,000 carats of gems, and 5,000 oz. of stones, which are ground and mixed with diamond dust for use in polishing gems. The Yogo gems occur in an igneous dike, which extends for some five miles through bodies of massive gray limestone. The stones are recovered by ground-sluicing and hydraulicking; the matrix of the stones disintegrating either in the sluices or by weathering, in similar manner to the blue clay matrix of the South African diamond fields. The output of the New Mines Sapphire Syndicate is shipped to Europe for cutting, and the product of The American Gem Mining Co. is cut by lapidaries in Helena, Mont. The Yogo sapphires are equal in quality and in value to the best Ceylon and Burma product. A further account of Montana sapphires, written by W. H. Weed, will be found

later in this section. In Cowee township, Macon County, N. C., sapphires are found in seams or layers in an altered hornblende gneiss.

At Anakie, in the Clermont district, Queensland, Australasia, sapphires to the value of £900 were mined in 1900. The stones are found under boulders in a wash not more than 3 ft. deep. The deepest workings do not exceed 14 ft. The wash is screened and sluiced and the stones recovered on tables by hand picking. The Withersfield Sapphire Co., Ltd., holds 240 acres of ground, which is expected to be actively developed in 1901. The production of sapphires for 1900 came from chance prospecting over a wide area of ground. The output of sapphires for 1900 in India amounted to 7,239 carats. In that year the New Kabue Gold Mines, Ltd., took over the lease of the sapphire mines at Pailin, Siam. The company leases the surface rights to native diggers.

**TURQUOISE.**—During 1901 seven mining companies were engaged in mining and marketing turquoise, mainly from the Cerrillos Mountains of New Mexico. The value of the total production from the United States during 1901 (most of which was provided by New Mexico) being \$118,000. Among the mines of New Mexico are the Blue Bell, situated 2.5 miles north of Cerrillos, and the Old Castilian, owned and operated by Tiffany & Co., of New York City. Other deposits of turquoise are in the Hatchitas and Cow Spring Mountains, near Silver City, N. M. The Silver City Turquoise Co. is operating a mine 1.5 miles northeast of Burros, Grant County, N. M. It is reported that an old turquoise mine, situated about 62 miles northeast of Manvel, San Bernardino County, Cal., is being operated with a small force of men by a New York company. Turquoise in some quantity and of good quality is reported from the Tonapah district of Nevada, at about 12 miles from Crow's Springs. The turquoise mines at Wady Maghara, in the peninsula of Sinai, which were again started in 1900 by the Egyptian Development Syndicate, produced a small quantity of turquoise of good quality during 1901.

**TOURMALINE.**—The disturbances in China caused the closing of the tourmaline mines in Mongmit, a Shan State, during all of 1901, for there is little or no demand for tourmaline outside of China. The jade mines of Myit-Kyina district, in Upper Burma were closed during the year for the same cause, although a little mining was done. The tourmaline mines of Mesa Grande, San Diego County, Cal., provided nearly all of the production of tourmaline in the United States during 1901, which amounted to a value of \$15,000. A new deposit of tourmaline a short distance from the older one promises an increased output for 1902.

#### MONTANA SAPPHIRES.

BY WALTER HARVEY WEED.

EARLY in Montana's history, when the "bars" of the Missouri river, near Helena, the terraces and side hill deposits of river gravels were being washed for gold, the riffles in the sluice boxes sometimes held pale greenish stones which were unnoticed at first, but identified later as sapphires. The discovery awakened but little interest at a time when gold alone was the object of search. From these early days to the present the river bars have been intermittently worked by nomadic

placer miners. About 1893 the locality was visited by European gem experts, who were impressed by the brilliancy of the stones and wrote most flattering reports, which confidently predicted that despite their unconventional color, they would become popular and highly prized gems. Heavily capitalized companies, which were organized abroad, acquired large tracts of land along the Missouri, and Montana was heralded as the new Golconda. Unfortunately these expectations were not realized. The stones were abundant and of high brilliancy, but their pale greenish color did not meet with popular favor, and Montana sapphires were a drug on the market. In 1895, as a result of placering for gold, the new Yogo field was accidentally discovered, and, as the stones were of the much-prized cornflower-blue color, they met with a ready sale. The property is to-day not only the most valuable gem mine in America, but the only place where sapphires are mined in the original matrix in which they were formed, resembling in this respect the Kimberley diamond mines of South Africa.

The Missouri river localities are located 12 to 18 miles from Helena. The different bars have received names—Ruby Bar, Spokane Bar, etc., and the gravels all contain sapphires as far up stream as Emerald Bar. These gravels are from 10 to 50 ft. thick, and situated at varying elevations above the stream (130 ft. at Emerald Bar). The gems are found in situ in a dike of igneous rock 3 miles below Cañon Ferry.

As investments these bar deposits have not been remunerative because the stones are chiefly of a pale greenish yellow color, and though very brilliant, are not highly esteemed by the public. Blue and red stones of fine color are extremely rare, and the pink and yellow ones not common enough to be counted upon in washing the gravel. The Missouri river bars are therefore not now worked, and the heavily capitalized corporations formed to mine the gems are financial failures.

The Rock creek locality is about 30 miles west of Anaconda and the same distance southwest of Phillipsburg, in Granite County. The sapphires occur in the gravels of several small streams forming the central headwaters of Rock creek. These placer claims have been extensively worked in the past three years, yielding several hundred thousand carats of rough stones, of which about 6% are fit for cutting. The gems occur only in stream gravels, but a few specimens are found in the original matrix of igneous rock. The gems from this locality, though greenish or blue-green, are deeper colored than those from the Missouri Bars, and meet with a ready sale in Montana, where they bring prices but little less than those of the blue stones.

The Cottonwood creek locality is about 10 miles east of Deerlodge, on the headwaters of the stream that flows through the town. The gems occur only in stream gravels, are of the usual pale greenish color, and the deposits have as yet been but little worked.

The Yogo mines, situated in the eastern footslopes of the Little Belt Mountains, are near the junction of Yogo creek with the Judith river, 15 miles from Utica, which is the nearest town, and accessible by stage from the terminus of the Montana railroad or from Great Falls. The gems occur in a dike of dark gray igneous rock, forming the sapphire vein, which has been traced for a distance of nearly five miles from the meadows of the Judith river across barren limestone hills

to the cañon walls of Yogo gulch and beyond. This remarkable dike, for the vein is a true dike of igneous rock, cuts white limestones (Carboniferous) and the red clays and dark shales which overlie them to the east. The gems occur in corroded forms and in well-defined crystals somewhat sparsely distributed throughout the rock. The dike rock is, when unaltered, of a very dark gray color and dotted with white and pale green inclusions. It consists of brown mica (biotite) and green pyroxene (diopside) and is classed as a basic *minette*. The inclusions consist of fragments of limestone or shale altered to calcite diopside and quartz.

The present workings consist of great open cuts, one of them 700 ft. long and 90 ft. deep, another 1,200 ft. long and 20 to 50 ft. deep, besides tunnel and shaft workings. Much of this open cut work has been done by hydraulic mining wherever the slope of the hillside permitted one end of the cut to reach the surface. The upper part of the vein consisted of a coarse breccia composed of fragments of altered limestone and shale in a yellow clay. These fragments diminish in amount in depth, and the mass of the dike is a yellowish brown clay, but this changes at 20 to 50 ft. in depth to a blue clay in which there are boulders and masses of the still fresh and undecomposed igneous rock. This blue clay, like that of the Kimberley diamond fields, is a product of the alteration of the igneous rock. It is a very important factor in the economical working of the mines, as it would be all but impossible to extract the gems from the original rock itself, whereas the blue clay disintegrates readily on weathering.

This material is worked by washing it into sluice-boxes similar to those used in ordinary placer mining for gold. The boxes are set with less fall than for gold and the riffles made slightly higher, as the sapphires are not so heavy as the gold, and hence would wash away. The "dirt" mined in the open cuts is screened and the fine material carted to the sluice-way to be washed, while the lumps are gathered in heaps to slowly disintegrate through weathering. This process is hastened by occasional wetting, which, with the freezing incident to the usual and almost nightly frosts of this altitude, aid the process. This disintegrated material is subsequently washed in the sluice-boxes. The material caught in the riffles is "cleaned up" and treated in an ordinary gold rocker fitted with three screens of different mesh. This eliminates much of the waste, and the resulting concentrate is panned by hand. The residual material consists of small irregular lumps of pyrite and the sapphires, and from this the gems are picked by hand. Formerly the small chips were rejected, but there is now a market for all the material, not only the larger gems, but also for the smaller ones for watch jewels. The stones are mostly small, a large proportion being flat discs showing the triangle (the so-called signature of the sapphire) in relief. Gems of 4 to 5 carats are rare. The largest stones found weighed from 11 to 12 carats and cut to gems of 5 to 6 carats. These larger stones are valued at \$75 a carat, but the smaller ones sell at retail at \$30 to \$40 per carat, according to the stone. In 1901 the output was about 150,000 carat of cuttable material.

*Origin of Sapphires.*—From the foregoing brief description it will be seen that the gems occur in dikes of igneous rock, both at Yogo and near Helena. The dike rock is different in the two localities, being a basic *minette* composed of only pyroxene and biotite at Yogo and an altered augite-mica-syenite in the Mis-

souri river locality. These are both very basic rocks, thus emphasizing the resemblance to the occurrence of diamonds in Africa. Sapphires have been formed artificially from alumina dissolved in molten glass, from which crystals separated out in cooling.<sup>1</sup> There is therefore no reason to doubt that the Montana gems originate from fragments of shale gathered from the walls of the fissure and carried upward as the liquid igneous magma filled the crack. These fragments dissolved in the liquid rock which then became extremely rich in alumina, which element, upon cooling, crystallized out as sapphires. It also seems certain that corundum is sometimes an original constituent of igneous rock.

---

<sup>1</sup> Morozewicz, *Zeitschrift fuer Krystallographie*, Vol. XXIV., 1896, p. 281.

## GLASS.

THE remarkable growth of the glass industry is shown by a comparison of the figures obtained from the Census Bulletin of 1900 for the decades 1890-1900 and 1880-1890, summarized respectively as follows: Number of establishments 355, against 294; capital \$61,423,903, against \$40,966,850; salaried officials, clerks, etc., number, 2,268, against 1,095; salaries \$2,792,376, against \$1,232,561; wage earners, average number, 52,818, against 44,892; total wages \$27,084,710, against \$20,885,961; miscellaneous expenses \$3,588,641, against \$2,267,696; cost of material used \$16,731,009, against \$12,140,985; value of products \$56,539,712, against \$41,051,004. The total cost of fuel in 1900 was reported as \$3,203,146, of which amount natural gas cost \$1,575,278, coal \$1,074,074, and oil \$409,158, the remainder being divided between coke and wood. Some Indiana establishments reported little or no cost for fuel, gas being supplied to them as an inducement for location, or because they owned their own gas wells. The cost of packages and materials for same was \$3,390,627 in 1900, against \$1,853,462 in 1890, an increase of 82.9%, due to the general demand for a safer and neater package and the increased use of the carton package for lamp-chimneys, etc. Soda ash was used in 1900 to the amount of 157,779 tons at a cost of \$2,259,939, against 96,777 tons, costing \$3,108,233 in 1890, the average cost per ton being \$14.32 and \$32.12, respectively, the decrease being due to the development in America of the soda ash industry.

The increase in the value of glass products between 1890 and 1900 was 37.7%, but probably the increase in quantity was in excess of this figure, especially in the output of bottles, jars, and glassware owing to the general introduction of the tank melting furnace and the adoption of improved mechanical equipment. The number of pieces of glassware, bottles, jars, etc., manufactured was not reported at the census of 1890, hence the impossibility of any comparison with the 1900 census. The total production of plate glass, rough and polished, in 1890 was 12,206,942 sq. ft., against 17,512,262 sq. ft. in 1900, an increase of 43.5%. The production of cathedral glass in 1890 was 2,773,824 sq. ft., against 8,846,361 sq. ft. in 1900, an increase of 218.9%. The outputs of skylight and wire glass in 1900 were 3,679,694 and 1,295,504 sq. ft., respectively, with no report for 1890. The production of window glass in boxes in 1890 was 3,768,884, against 4,341,282 in 1900, an increase of but 15.2%, which is accounted for by the shorter "run" during the "fire," the average "run" being about 6 months in

1900, against nearly 10 months in 1890; besides, labor was very scarce during 1900.

In addition to the 355 active establishments in 1900, there were 60 establishments idle during the census year, no account being taken of the permanently deserted and abandoned factories. Of the 60 idle factories, 41 with a capital of \$2,296,587 manufactured pressed and blown ware, or bottles and jars. The remaining 19 idle works were building glass manufactories with a capital of \$1,247,949.

*New Establishments.*—The following companies were incorporated or announced to be incorporated during 1901: In April, 1901, the Mississippi Glass Co. was organized in New Jersey with a capital of \$1,500,000 to control the output of wired glass in the United States, and consolidated the following companies: the Mississippi Glass Co., the Besto Glass Co., the Wire Glass Co., of Pennsylvania; the American Wire Glass Manufacturing Co., and the Appert Glass Co. The glass is being produced at the works of the Mississippi Glass Co. at St. Louis, and the Appert Glass Co. at Port Allegheny, Pa. Announcement was made of a recent order of 100,000 ft. for the Japanese Government, and that the use of wire glass for fireproof shutters of large buildings was increasing. Prices announced were 15c. per sq. ft. for 0.25 in. glass in stock sheets. The Columbia Plate Glass Co.'s new \$1,000,000-plant at Blairsville, Pa., with an annual capacity of 1,500,000 ft. of glass, is expected to be in operation by June 1, 1902. Early in 1902 the new window glass plant at Danville, Ill., was started. The plant employs about 150 men, and is the largest in the State. It is expected that a large glass plant will be established about the middle of 1902 at Stockton, Cal., at a cost for plant of \$60,000. An Eastern concern will move its plant to this place with its 150 employees to take advantage of an exceptionally fine deposit of manganese ore (used for tinting glass) near Tesla, close to Stockton. The Atlas Glass & Metal Co., capitalized at \$1,000,000, was organized in West Virginia during the latter part of 1901 to operate factories at Wheeling and Clarksburg, W. Va., and Washington, Pa. The Yonkers Glass Co., capitalized at \$100,000, was organized early in 1902 in New Jersey. The Ohio Glass Co., with a capital of \$50,000, was organized to operate a factory for the manufacture of prescription bottles, at Sisterville, O.; the factory will cost \$30,000, and it is expected to be in operation early in 1902. The Diamond Cut Glass Co. was organized early in 1901 to manufacture cut glass in Jersey City, N. J.; the capitalization is \$50,000. The Kokomo Glass Manufacturing Co., capitalized at \$35,000, was organized late in 1901 to manufacture glassware at Kokomo, Ind. During the latter part of 1901 the New Martinsville Glass Co., at New Martinsville, W. Va., increased its capital stock from \$50,000 to \$100,000.

*Tariff Decisions.*—In a circular dated May 7, 1901, the Treasury Department announced that the custom of assessment which prevailed for some 80 years previously would be altered from assessing on plate and window glass by superficial area in square inches, to arbitrarily bracketing the sizes by length and breadth measurement of the piece without regard to the number of square inches contained therein, also that the ruling would apply on all glass imported after September, 1900, thus compelling the jobbers to pay the excess duty on glass sold under

the old ruling for nearly a year. The duty had been paid under protest by importers at St. Louis and Boston, but New York, Philadelphia, Chicago, Cincinnati and Louisville escaped until the lack of uniformity brought to the attention of the department, resulted in the circular of May 7, 1901. The effect of this decision is virtually to exclude the long narrow strips of glass which were formerly sold by foreign manufacturers at less than cost prices, and is a corresponding benefit to American manufacturers.

*Review of Prices.*—The Independent Glass Co., which had a working agreement with the American Window Glass Co., during 1900, was incorporated early in 1901. A new list was issued under date of January 21, 1901, by the National Window Glass Jobbers' Association, which announced the following discounts to the trade: less than car lots, 88%; car lots, 90% from list. These prices were universal for single and double strength glass. In March prices were advanced to 85% and 5% for less than carloads, and 87.5% in carloads. In April discounts were 85% for less than car lots, and 85% and 10% and 2.5% for carloads. In May, and from thence on to November 1, the prices were 80% and 20% discount for less than carloads, and 85% and 5% for carloads. When the furnaces went out of blast at the customary time early in May the outlook was most favorable, the market was strong and the stock on hand was a little less than normal. In November the competition of outside factories and imported glass resulted in a ruling of the Jobbers' Association, permitting jobbers generally to establish their own prices, and later in the month the prices were made 90% discount for less than car lots from store; 90% and 7.5% discounts for carloads from store, and 90% and 12.5% discount for carloads f. o. b. factory. Later in the year these prices were shaded materially in the attempt to force outside glass factories into a price agreement with the result that the year closed with a demoralized market.

*Germany.*—Two important glass works of Germany are situated in the district of Brunswick, both of which export important quantities of optical and plate glass to the United States annually. The Deutsche Spiegelglas Actien Gesellschaft, at Freden, Province of Hanover, manufactures plate glass and lenses for eyeglasses. The incorporated firm of Voigtlaender & Sohn Actien Gesellschaft manufactures optical glass and scientific instruments. Recently the firm established a branch factory in the city of New York, U. S. A. During 1900 the value of the optical and plate glass shipped from the district of Brunswick to the United States amounted to \$82,193, the value of the scientific instruments being \$1,379. The factory of Voigtlaender & Sohn was established in the city of Brunswick in 1756. It employs 260 hands and has a staff of 15 foremen who have had technical education. Among the articles manufactured are photographic objectives of all sizes and systems; euryscopes; astigmatic collinears, and apochromat-collinears, used by photographers and for process work of all kinds. Recently in the construction of its instruments the firm introduced a new alloy of aluminum and magnesium called magnalium, which greatly reduces their weight and renders them weatherproof. The short rifle telescope, in general use by sportsmen in Germany, is one of the specialties of this firm.

The glass factories of Lorraine, numbering four, make glassware of all kinds

and prices—watch glass, spectacle glass, lamp glass, window glass, glass for pendules and for scientific instruments, etc. Most of the output is exported to the United States and other countries. The increase in the export trade in glass from Lorraine is shown by the following figures: \$67,177 for 1898, \$139,498 for 1899, and \$177,576 for 1900.

*Roumania.*—Four glass manufacturing works supply Roumania with about all the cheap glassware it can consume. The works established at Azuga, with office at Bucharest, is owned by a limited corporation, and produces from \$77,200 to \$96,500 of glassware annually, working three shifts of laborers per 24 hours. Their products are colored, ordinary and cut, hollow glassware and engine-turned glass articles. The factory at Bogdanesci, in the district of Bascau, is owned by the Weisengrun firm of Jassy, employs from 80 to 100 workers, and manufactures annually ordinary hollow glassware valued at about \$38,600. The rather primitive glass works at Storesci, in the district of Botosani, produce hollow glassware of the common type, cylinders for lamps, medicine and ink bottles, etc., the annual output amounting to from \$19,300 to \$28,950. The factory at Heci-Lespezi, in the district of Succava, has two Siemen's gas-ovens, employs 200 hands, and manufactures, besides ordinary hollow glassware, fine, cut, white and colored goods, largely sold in Roumania, but to some extent in Bulgaria and Turkey. The factory for the manufacture of glass plates at Ciobanesci, in the district of Bascau, was established early in 1900 and has a capital of \$77,200. The importation of cheap or ordinary glassware into Roumania amounts to practically nothing, but there is a small market for the better quality of articles.

*Technology.*—A process for producing glass vessels of an unusually large size was invented during 1901 by Paul Sievert, of Dresden, Germany, which consists in pouring the liquid glass on a cast-iron plate, where it hardens as soon as it reaches the projecting edges. The still refractory glass frees itself from the plate (the hardened edge remaining fast) and forms an elongated sack, the bottom of which rests upon a table. Compressed air is conveyed to the sack by means of a hollow cylinder and a plate pierced with holes, and the sack is blown to the required size while the table is being lowered. While the table continues to sink, the upper glass edge is freed by the removal of the projecting edge of the plate and the finished vessel is allowed to cool. Formerly concave glass vessels above 26.4 gal. capacity could not be blown, but it is stated that bath tubs and large kettles may be blown by the new method. An electrical method reported to be in use in Cologne, Germany, is described as follows: The components of the glass after mixing are exposed on a series of platforms arranged in steps, to the action of the voltaic arc. The fusion is gradually increased on the succeeding steps, and at the foot of the staircase furnace the material falls into a receiver which communicates with a second receiver at the bottom, where it is cleansed of its impurities, and finally reaches a third receiver from which it is taken to be worked.

A proposed method of M. Leon Lemal for coloring glass by penetration is described as follows: A little silver salt is sprinkled on the surface of the glass, which is then heated to 500° or 550°C. When the excess of salt has been removed the surface of the glass appears yellow, the color penetrating to a depth of

0.17 mm. after 5 minutes of baking. In an hour double that depth would be colored; after 18 hours the glass would be penetrated through 1.6 mm. of depth. To transfer a lace pattern on glass, the lace should be dipped in a 0.001 solution of silver nitrate and then into potassium sulphide. It is reported that colored monograms may be obtained in this way, and that ordinary collodion negatives can be printed on glass in various colors by this method; silver and copper give a red, and gold and iron salts have also been used. When the baking is continued for a long time the coloring matter should be renewed every six hours.

United States Patents Nos. 688,923 and 688,924, of December 17, 1901, issued to G. W. Blair and H. J. Hays, cover a window glass blowing machine, which is expected to be in use during 1902. According to the specifications, the cylinders are formed over a circular mold centrally projected through the surface of the molten glass in the furnace, by the insertion of a properly shaped dome-like metallic gathering head of circular form over and around the orifice and into the fluid glass surrounding it, which adheres to it as it would to a blowpipe. The cap or gathering head is then withdrawn slowly, the glass adhering to it forming the beginning of a hollow glass cylinder, which is increased in size by air interiorly supplied through the projecting orifice of the gathering head. This projecting orifice prevents the cylinder from collapsing while it is being drawn upward through the furnace-crown, or suitable glass-holding receptacle. The machine in question has been under construction in Allegheny, Pa., during the past three years.

A machine for blowing glass bottles, etc., has been perfected by M. Claude Boucher, of Cognac, France, by which one workman with two assistants is able to turn out 600 bottles weighing from 600 to 700 g. each, in from 10 to 11 hours, the blowing being done by compressed air. For a detailed account of this invention reference should be had to the *Bulletin de la Société d'Encouragement*, May 30, 1901.

## GOLD AND SILVER.

THE production of gold in the world during 1901 was 12,812,792 fine oz., valued at \$264,840,477, as compared with 12,614,633 fine oz., valued at \$260,743,830 in 1900. This slight increase was due chiefly to the United States, Mexico, Russia, Rhodesia and Australia.

The United States continues to occupy the foremost position as a gold-producing country, with Australia second, Russia third, and Canada fourth. These four countries produced in the aggregate nearly 80% of the total world's production of gold in 1901. The largest individual increase in gold output was in Russia amounting to 181,152 oz., valued at \$5,744,543, while the Transvaal, which was the chief producer in 1898, contributes an output even less than in 1900, the total production for this country in 1901 being but 238,991 fine oz., valued at \$4,939,944. Deducting the Transvaal output from the grand totals for 1900 and 1901, the statistics show an increase in the other gold-producing countries of \$10,171,000 for 1900, and \$6,366,572 for 1901.

(a) Figures based on exports of ore, matte, etc., and coinage. (b) Computed from exports. (c) As reported by the *Statistique de l'Industrie Minière*. (d) Production from domestic ores. (e) Estimated. (f) Includes six States and New Zealand. (g) Includes Serbia, Persia, West Indies, Formosa, British New Guinea and Philippine Islands. (h) Estimate furnished by Mr. George E. Roberts, Director of the United States Mint.

NOTE.—The value of gold is \$39.67 per ounce, which is equivalent to \$664.60 per kilogram.

The production of silver in the world during 1901 amounted to 174,851,391 Troy oz., valued at \$102,769,792, as compared with 180,093,364 Troy oz., valued at \$110,451,012 in 1900, showing a decrease in production of 5,241,973 oz. The United States continued to occupy the foremost position as a silver-producing country, followed by Mexico, these two countries producing collectively 60% of the total output of silver in the world during 1901. The production of silver in Germany is derived largely from imported ores and bullion, and consequently

should be credited to other countries as has been done in the subjoined tables.

## PRODUCTION OF SILVER IN THE UNITED STATES.

(a) Statistics compiled from exports and coinage. (b) Exports of silver in all forms. (c) Silver produced from domestic ores only. (d) The output is mostly from China and Persia. (e) Estimated. (f) Estimate furnished by Mr. George A. Roberts, Director of the United States Mint.

NOTE.—Unless specified to the contrary, the statistics have been taken from official sources or have been collected directly from the producers by THE MINERAL INDUSTRY. The average commercial value of silver for 1900 was 61.23c. per ounce, which is equivalent to \$19.718 per kilogram. The value for 1901 was 58.95c. per ounce, equivalent to \$18.963 per kilogram.

THE WORLD'S PRODUCTION OF GOLD.

From the year 1875 until 1899 the annual production of gold in the world increased from 173,904 kg., valued at \$115,576,598 to 468,695 kg., valued at \$311,505,947, a gain of more than 170%. During this period there was but little change in the annual output, the totals ranging between the largest record of 185,847 kg. (\$123,513,916) for 1878, and the smallest record of 144,727 kg. (\$95,185,564) in 1883. From 1890 when the production amounted to 181,256 kg. (\$119,600,000) the growth has been very rapid, owing chiefly to the application of the cyanide process in treating refractory ores and tailings, the development of the South African fields and the discovery of new gold fields in Alaska.

THE WORLD'S PRODUCTION OF SILVER.

## PRICES OF SILVER.

The average prices of silver in New York and London, as computed by *The Engineering and Mining Journal*, are shown in the subjoined table. The higher average in 1900 was due to the demand for coinage in the East and extensive use in the arts.

| Month.        | 1899.             |                     | 1900.             |                     | 1901.             |                     | Month.         | 1899.             |                     | 1900.             |                     | 1901.             |                     |

NOTE.—The New York prices are per fine ounce; the London quotations are per standard ounce, which is 0.995 fine.

## GOLD AND SILVER MINING IN THE UNITED STATES DURING 1901.

The production of gold and silver for the years 1901 and 1900 may be obtained from the detailed tables in the early part of this section.

*Alaska.*—(By William M. Brewer.)—Since the discovery of gold in the Klondike, the attention of prospectors has been directed to the numerous islands of Alaska and to the coast line from Portland Canal to Behring Sea. From Ketchikan as the central point, exploring parties have followed the coast lines and penetrated into the interior of Prince of Wales, Revillagigedo, and the smaller islands in search of ore deposits. As a result of this search deposits of auriferous quartz have been found at Hollis at the head of Cassau Bay and on Karta Bay, Prince of Wales Island, also on Thorne Arm in Revillagigedo. At the latter locality the quartz occurs in a belt of schistose rock, which apparently occupies an extensive zone in southeastern Alaska. Extensive mining operations have been conducted for some years at Berner's Bay on the mainland, northwest from Port Wrangel. In the Porcupine district, inland from Pyramid Harbor, placer gold was discovered in 1899, and the deposits have been worked since that date. There seems to be a good future for the mining industry in the southeastern portion of Alaska, as this part of the territory has the special advantages of mildness of climate, cheap transportation and low cost of fuel and supplies.

*Nome District.*—During 1901 mining was much handicapped by litigation over claim titles, as well as by the shortness of the working season, which was fully two months late, and closed at the usual time in the fall. Drilling operations on the tundra which were commenced in 1900 continued throughout 1901, and resulted in the discovery that a large part, if not all, of the gravel underlying the tundra will pay to work. The tundra, or moss, is about 8 ft. deep, and between the tundra and bed-rock is a layer of gravel from 40 to 80 ft. deep which bears gold in quantities varying from a few cents to \$12.50 per cu. yd. After bed-rock is reached it is estimated that by using a 6 to 8-H.P. boiler for thawing, with 4 gangs of 3 men each, the average cost per cu. yd., including coal, will be \$8.50. A New York company pursued investigations with a Keystone boring drill during the entire season, winter as well as summer, and found that the gravel was not frozen below the tundra, that the tundra itself could be used for fuel, and that the values ranged from \$3.64 to \$12.41 per cu. yd. The bench claims of Anvil creek proved even richer than the creek claims: Dry, Extra Dry, Bourbon, Dexter, Buster, Mountain, Rock, Specimen, Nikola, and Snow were large producers, while smaller creeks are rapidly becoming payers. Three bench claims on Glacier creek have discovered the old channel on their property, and are very rich. Owing to their inland position, and the frozen condition of the country, the Koogrock, Bluestone, and Casa de Pogra districts have not been developed to the point of rivaling Nome as had been expected. Outside of Anvil creek, Ophir creek in the Eldorado district, which probably has more paying claims in proportion to its length than any in Alaska, together with its tributaries, has produced over \$1,000,000, despite the shortness of the season. Of the new districts Good Hope Bay and Candle creek are being vigorously boomed, but authentic information of the amount of gold obtainable is lacking. In the Solomon river country several

dredging plants are expected to be in operation in 1902 on the low-grade gravel deposits which are of immense size. The development of the deposits in the vicinity of Nome has been and will be much handicapped by the governmental policy of permitting claims to be staked by proxy. Especially in the creek claims, assessment work is often falsely reported as accomplished and as evidence is obliterated with the spring rains, much deception is practiced; even the bench claims are not free from suspicion. But as relocation involves a lawsuit, several years will elapse before all the older deposits are thoroughly explored.

**Juneau and Other Districts.**—The Alaska Treadwell Gold Mining Co. mined and treated 457,802 tons of ore for a yield of \$559,126 (\$1.22 per ton) in free gold and \$301,611 (66c. per ton) in sulphurets, a total of \$860,737 or \$1.88 per ton. In addition there were on hand at the close of the year 845 tons of sulphurets valued at \$35,422, which brought the total gold production up to \$896,159 or \$1.96 per ton as compared with \$1,153,368 or \$2.07 per ton in the preceding year. The total working costs were \$483,319 (\$1.0557 per ton) and the construction expenses amounted to \$62,649 (13.69c. per ton), while the net profits were \$352,559 (77.01c. per ton). Dividends amounting to \$300,000 or 6% on the capital stock were paid and the remainder of the profits carried over on the surplus account. The estimated amount of ore in sight and available for the mill on May 15, 1901, was 3,917,589 tons. The Alaska United Gold Mining Co., owning the Ready Bullion (120 stamps) and the 700-Foot (100 stamps) mines adjoining the Alaska Treadwell on Douglas Island, reports for the year ending December 31, 1901, as follows: the Ready Bullion milled 171,642 tons of ore averaging \$2.01 per ton in value for a yield in gold of \$1.3096 per ton free, and \$0.6326 per ton in sulphurets. Total costs including construction account was \$1.8574, leaving a net profit of \$0.0848 per ton. The 700-Foot mine stamped 89,840 tons of ore averaging \$2.21 per ton for a yield in gold of \$1.0105 per ton free, and \$0.4849 per ton in sulphurets. Total cost, including construction account, was \$1.9738 per ton, produced at a net loss of \$0.4785 per ton. The total receipts for bullion from both mines was \$465,184; total operating expenses, including interest and coal shortage, was \$504,649, showing a net loss of \$39,465 for the year. The amount of ore blocked out in both mines at the close of the year was 527,604 tons. The Rodman Bay mines on Baranoff Island, 60 miles from Sitka, are being developed by an English company. An 8-mile railway and a 150-stamp mill, which will be completed in 1902, will enable the company to work profitably its immense low-grade gold deposits. The ore ranges from \$3 to \$4 per ton in gold. The Olympia Mining Co., on Woewadski Island (near Wrangel) during the year operated a 20-stamp mill on ore yielding \$7.50 per ton. The Yellow Jacket Co., owning four quartz claims on Windham Bay, completed a wagon road 1.5 miles long to its property, and has a 10-stamp mill en route.

**Alabama.**—There was a small production of gold in 1901 which came from the mines in the Arbacoochee district of Cleburne and Randolph counties.

**Arizona.**—There was considerable activity in Yavapai County, especially about Wickenburg and Congress and in the region east of Prescott. An important development has been the construction of the Poland-Lynx Creek tunnel which when completed will give improved transportation facilities to the

Lynx Creek district and will also form an outlet for the Poland-Hamilton mines. The workings of the Congress mine have reached 3,250 ft. in depth, but the output is still well maintained. The Mud Hole mine, which is operated by the Penn Mining Co., has increased its plant to 120 tons daily capacity. Some good strikes were reported in the Chloride district which gave increased impetus to development operations. Tombstone may once more be an important mining center, as the consolidation of the mines will facilitate their development on a larger scale. There was considerable activity shown in prospecting in Cochise and Pima counties and numerous deposits are being developed some of which carry gold and copper. The Rio Del Monte mine near Marqua Hala has commenced the erection of an 80-stamp mill, and a large cyanide plant is in process of construction at Gold Basin. With the renewed interest that is shown in the mining industry, it seems probable that the Territory will give an increased output of gold in 1902.

*California.*—The gold mining industry showed some expansion despite the unfavorable conditions of rainfall that prevailed in 1901 as in the two preceding years. With a normal water supply the output would have been largely in excess of that of 1900, as a great many of the old mines were prepared under favorable circumstances to extend their operations, while the number of new producers would have been increased. The use of the steam dredge for working low-grade river gravels has proved a success in several localities, particularly on the Feather, American and Klamath rivers and the number of plants in successful operation is being increased. Large tracts of land have been purchased around Oroville and other points where the conditions are favorable for this class of work. In Butte County alone there were 12 companies engaged in active operations during 1901, while the total for the State was 25 companies with 26 dredges constructed and eight to be built. The actual capital invested in the industry is said to be not far from \$2,500,000. The types of dredges used include the Risdon, Eucyrus, Urie, and Marion. Hydraulic mining was carried on in the drainage basin of the San Joaquin and Sacramento rivers, but the center of this industry has been transferred to the northern part of the State, where the laws are not so rigorous in regard to the impounding of tailings. The conditions here are very favorable for hydraulicking, enabling low-grade gravels to be worked at a profit. One company operated during the year 1900 at the phenomenally low cost of 2½c. per cu. yd.

*Colorado.*—This State which for several years has occupied first place in the output of gold, produced 1,339,112 oz., valued at \$27,679,415 in 1901 against 1,391,486 oz. and \$28,762,036 in the preceding year. The output of silver amounted to 18,492,563 oz. against 20,336,712 oz. in 1900. Teller County continued far in the lead as a gold producer, while Lake, San Miguel, Gilpin, and Ouray counties followed in the order named. The Cripple Creek district of Teller County increased its tonnage of ore shipped but the value of the product was somewhat less. The smaller mines in this district did not contribute as much as usual to the total, while some of the large producers were hampered in their operations by water, and the necessity of giving increased attention to development work. Stratton's Independence, Ltd., from November 28, 1900 to Septem-

ber 20, 1901 produced 66,199 tons of shipping ore with a gross value of \$2,506,862, from which a profit of \$1,067,000 was realized. These totals were in excess of the estimates made by Mr. John Hayes Hammond, under whose direction a large amount of development work was carried on, resulting in an increase of ore reserves and important economies in working costs. The main shaft was sunk 400 ft., while 7,288 ft. of drifts and cross-cuts were run, the total expense of the development work being \$213,740. No payable ore bodies were found below the 1,150-ft. level, but it was deemed advisable to prosecute the work inasmuch as some of the neighboring properties have shown zones of pay ore succeeding poor ones in depth. The Portland Gold Mining Co. reported a production during the calendar year 1901 of \$2,408,413, from which a profit of \$1,760,939 was earned. Other mines which were active and important producers during the year were the Gold Coin, Elkton, Doctor-Jack-Pot, and Gold King. It is thought that the lower rate of treatment charges on low-grade ores that was conceded by the mills and the reduction of freight charges by the railroads will react favorably upon the output in 1902. In the Leadville district, the year's operation resulted in the extension of the gold producing territory. The Smuggler-Union Mining Co. in San Miguel County was handicapped by a strike of the union workmen which lasted from May 1 to July 7, and by the destruction by fire of buildings at the Bullion tunnel. Important improvements were undertaken, including the construction of a cyanide plant of 400 tons daily capacity and the rebuilding and enlargement of one of the two mills at Pandora. The company shipped 23,799 oz. bullion to the mint and 10,792 tons of ore and concentrates to the smelters. The holdings of the Tomboy Gold Mines, Ltd., were increased by the purchase of claims carrying the Argentine claim, and it is proposed to build a new mill and make other improvements during 1902. For the year ending June 30, 1901, the company's report showed an output of \$649,281 bullion from which after paying all charges a profit of \$218,585 was realized. The new chlorination mill now building for the Portland Co., at Cripple Creek, is expected to be in operation before the middle of 1902. The mill will contain heavier crushing machinery than usual, three 60-ft. diameter Pearce turret furnaces—the largest ever built—and twelve 10-ton chlorination barrels; all buildings are steel construction, and the capacity of the plant will range from 450 to 500 tons per day. A consolidation of eight mining companies of Cripple Creek along the line of the United Mines tunnel (now 9,462 ft. in length) has been effected by the Woods Investment Co. The new company is capitalized at \$5,000,000, divided into \$1 shares.

*Georgia.*—The Dahlonga Consolidated Gold Mining Co. has employed about 100 men at its mine and mill on the Hand property during 1901. Considerable shafting and drifting was done during the year, resulting, according to report, in the blocking out of considerable bodies of ore ranging from \$8 to \$12 per ton in gold. Neither the plates nor the concentrators seemed to catch the fine gold, the recoveries from ore of \$10 per ton ranging from \$2 to \$3, and after successful experiments the company began the erection of a Hicks barrel process plant. Early in 1902 the Dahlonga Gold Mining & Milling Co., of Chicago, Ill., capitalized at \$2,500,000, was organized to operate placers and quartz veins on

its 710-acre tract. The company proposes to build a 50-stamp mill. In May, 1901, announcement was made of the organization of the Georgia Dredging Co., capitalized at \$500,000, for the purpose of operating gold dredges on the Etowah river. Several dredging companies were in successful operation on the Chestatee river during 1901. Experiments were made with a suction pump to work such river bottoms as are filled with jagged rock, and also the saving of the black sands said to contain from \$20 to \$100 per ton in value was attempted. The Columbia Gold Mining Co., of McDuffie County, milled 1,146 tons of ore during 1901 for a yield of \$7,272.

*Idaho.*—The gold mining industry was fairly successful in this State during 1901 and the output showed a moderate increase to which both alluvial and quartz mining contributed. The finding of gold at Thunder Mountain, near the central part of the State, created considerable excitement, but as the discovery was made late in the year, no extensive developments were possible, and the value of the ore bodies is still unproved. According to the best authenticated reports, there is a large mass of low grade material which contains some good pay streaks. The values are disseminated through the rock, apparently forming no well defined lodes. At the De Lamar mine, work on the tunnel was suspended about the middle of the year, but prospecting was continued by diamond drill which located a small ore body that still awaits exploration. As the end of the ore reserves had been practically reached, the operations during the year were of limited character. Dredging on Snake river has become an established industry. The Sweetser-Burroughs Mining Co. has two boats in operation near Minidoka, one of which was built in 1894 and the other in 1899. According to Robert Bell (*The Engineering and Mining Journal*, February 15, 1902) the cost of handling the river gravel ranges from 4.5c. with the suction dredge to 5.5c. with the chain elevator bucket type. The method employed in saving the gold consists in discharging the gravel onto a stationary sluice from which it passes to two stationary sluices with perforated steel bottoms with 0.125-in. holes. The coarse materials from the screens is carried on a rubber belt to the stem of the boat, where it passes into the river. The fine material is discharged into a distributing box which feeds it evenly to a set of burlap tables which discharge over the side of the boat. The burlaps are taken up at intervals of six or eight hours and washed in a wooden tank, from which the accumulated gold and black sand concentrates are elevated automatically to the amalgamating room, where the gold is amalgamated and retorted.

*Montana.*—The Fergus Co. mines produced actively during the year and several new plants were erected. Large cyanide plants were erected in Lewis and Clarke counties, as described elsewhere in this volume under the caption "Review of Progress of Cyanide Industry during 1901." A number of small stamp mills were erected and put into operation in Madison County. In Granite County a 600-ton concentrator equipped with Brückner chloridizing roasters, and pan-amalgamation plant, the whole to be operated by electricity, was completed during the latter part of the year. The report of the Montana Mining Co., Ltd., for the year ending December 31, 1901, shows a total of 25,122 tons of ore treated for a yield of \$122,131, at a cost for mining, milling, and prospecting of \$231,555,

the operation for the year resulting in a loss of \$109,424. During the year 96,303 tons of tailings were treated for a yield of \$247,560 in gold and silver, at a cost of treatment and handling of \$102,117, resulting in a profit of \$145,443. Deducting the loss in stamping, the profit for the year was \$36,019. No dividends were declared, but the Lucky Girl group of mines, at Edgemont, Nev., was purchased at a cost for mines and equipment of \$158,690, which was paid for from accumulated surplus. A large cyanide plant will be erected on the property. The most important purchase of mining property during the year took place in September, when the Boss Tweed and Clipper group of mines at Pony, Madison County, was bought by A. C. Burrage, of Boston, for \$600,000; a 100-stamp mill is in course of erection on the property which has an immense tonnage of low-grade gold ore having a width of 90 ft.

*Nevada.*—The development of the Tonapah Lake district, in Nye County, by a system of small leaseholds has proved a bonanza for the lessees. Their shipments for the year aggregated \$1,000,000 of ore averaging \$18 $\frac{1}{2}$  per ton, and some 30,000 tons of ore worth \$125 per ton remain on the dumps awaiting shipment. The ore is very siliceous, and for smelting requires the addition of 1.25 tons of iron, copper, or lead ore, to 1 ton of Tonapah ore. The ratio of gold to silver in the ore is approximately 1 to 2. Test runs made in stamp mills on the Carson river claim a saving of 88.5% of the gold and silver values. The company owning the mine has cancelled the leaseholds and proposes to have a 20-stamp mill in operation early in 1902. It is estimated that the Tonapah Mining Co. of Nevada, which purchased the mines early in 1901 for \$336,000, has received during the year, its entire purchase price in royalties. The 100 lessees have blocked out large bodies of ore which they were unable to remove. Transportation facilities are lacking, ore and supplies must be hauled by wagon, and for a long time water was sold for \$1 per barrel. Springs are being piped to the camp of 1,200 inhabitants which has sprung up during the year, and wells have been sunk with the result that water is now available. At Ely, in White Pine County, the Chainman Mining & Electric Co. has completed a 150-ton wet crushing cyanide plant, containing the following machinery: Gyratory crusher, 1 set roughing rolls, 2 Chilean mills, 400 ft. amalgam-plates, 8 Cammett concentrators, 4 settling tanks 26 ft. square, 8 leaching tanks 28 ft. square, 2 vacuum pumps, 2 solution pumps, 2 filter presses, and 1 air-compressor. The De Lamar zinc-dust precipitation process is provided for and a complete refinery installed. The daily capacity of the mill is 225 tons of slimes. The plant is equipped to run by electricity from Ely, two miles distant. It is said that the ore yields \$2.50 to amalgamation, 1 ton of \$100 concentrates from 100 tons of ore, and the balance to the cyanide.

*North Carolina.*—(By Joseph Hyde Pratt.)—There are at present about 15 mines in operation located in Cabarrus, Mecklenburg, Stanly, Montgomery, Burke and Rowan counties. The principal developments have been confined to the vicinity of Gold Hill, Rowan County, about 14 miles S.E. of Salisbury. The region is made up of chlorite and argillaceous schists which are cut by diabase dikes and enclose bands of schists impregnated with auriferous pyrite and quartz veins and stringers. The Whitney Reduction Co. has been developing its property for

two years. Its property embraces 30,000 acres of mineral, farming, and river lands. Three shafts, one of which is 600 ft. deep, have been sunk, and a 10-stamp mill and chlorination plant have been making test runs for a year. The proposed power dam on the Yadkin river, 14 miles distant, will be erected in two years' time, and the company will then erect a 100-stamp mill. The Gold Hill Co. has erected a 20-stamp mill and made all preparations to treat the large body of ore blocked out in the old Randolph mine. Among the other producers of gold in 1901, are the Parker mine in Stanly County, the Champion mine in Mecklenburg County, and the Martha and Mills mines in Burke County.

*Oregon.*—The gold yield for 1901 from the mines in the vicinity of Sumpter, Baker County, is estimated at over \$3,000,000. The ore is quartz carrying considerable pyrites, but is easily mined and milled, and the cyanide process saves a large per cent. of the gold. One of the most promising new properties is the Oregon King, directly south of the North Pole, and Golconda, two of the largest producers in the district. The Oregon King will erect a 10-stamp mill and cyanide plant for the tailings, besides putting in a giant to work their placer ground. The Old Channel Co., in Josephine County, has widened its 12-mile ditch to a capacity of 5,000 miners' inches, and with four giants has reduced the cost of handling gravel to 25c. per cu. yd. The Stirling Co., on Forest creek, gets its water to operate two giants for 9 months in the year, from a 25-mile ditch carrying 2,500 in. of water from Glade Fork. The gold is found in a red clay gravel deposit.

*South Carolina.*—(By Joseph Hyde Pratt.)—The chief source of the gold produced in this State is the Haile mine in Lancaster County about three miles N.E. of Kershaw. A 60-stamp mill, 20 concentrators and a chlorination plant are in operation, and the mine is well developed. The ore bodies are lenticular in shape and carry both free gold and auriferous pyrite. At Abbeville somewhat similar ore bodies are being worked by the Kendricks Gold Mining Co.

*South Dakota.*—The principal feature of the mining industry in the Black Hills was the starting up of a number of new cyanide plants for treating low-grade refractory ores and mill tailings. The increment of production from these sources cannot be ascertained with any degree of accuracy, but doubtless it was considerable. One of the largest plants having a capacity of 1,200 tons per day was put in operation by the Homestake Mining Co. and proved a financial success from the beginning, as did the smaller plant of the Fortland Co. For details relative to the cyanide process as used in the Black Hills the reader is referred to the review of this subject by Charles H. Fulton on page 339 elsewhere in this volume. Construction work was started late in the year on a new smelter at Rapid City which will have a daily capacity of 500 tons. The report of the Homestake Co. for the year ending June 30, 1901, showed a return of \$3,569,205 in bullion, or \$3.82 per ton of ore, which was 20c. less per ton than in the preceding year. The total expenses were \$3,296,517, leaving a balance of \$421,566 after including receipts of \$18,305 for concentrates sold, \$2,772 for siliceous ore and \$78,851 from other sources. The dividend distribution during the fiscal year was \$1,260,000. Dr. C. C. O'Harra, in a paper read before the International Congress, at Boise, Idaho, July, 1901, classifies the gold deposits of the Black

Hills into (1) Recent placers. (2) Cambrian cement or conglomerate. (3) Auriferous quartz veins, in the Algonkian slates. (4) Impregnated zones in the Algonkian schists and slates and (5) siliceous ores of the Siluro-Cambrian and Carboniferous series. Of these classes, one and two have been practically exhausted, class three is now receiving much attention, the ores being found S.W. from Deadwood around Bald Mountain and of lesser extent in the galena district, S.E. from Deadwood. The ore veins occur in extended lenticular masses running north and south and of a thickness up to 15 ft., a width up to 200 ft., and often more than a mile in length. Narrow vertical fissures filled with ore continually follow the general trend of the flat ore bodies and frequently extend into the overlying shales and the underlying quartzite. The chief horizon is just above the quartzite near the bottom of the Cambrian series. The value of the Siluro-Cambrian ores ranges to \$60 or more in gold and some silver, averaging in total value from \$15 to \$20. Ore less than \$10 is generally not worked. The annual production of gold in the Black Hills has continually increased during the past few years, owing to two causes: first, the increased development of the siliceous ores both in the Siluro-Cambrian, the most extensively worked, and in the Carboniferous, the most recently discovered, through the development of the cyanide process for treating the ores; and second, by the considerable enlargement of the Homestake plant, now the largest cyanide plant in the district operating on the tailings formerly allowed to waste. The silver output remains uniform, being approximately \$100,000 for the year. The chief localities are those of Carbonate, Galena and Spokane, carbonates, chlorides and sulphides are the chief ores.

*Tennessee.*—The placer deposits of Coker creek, Monroe County, were operated by four or five companies with some success. One company has done some exploration work on quartz veins carrying free gold, but the ore has not been treated on a commercial scale.

*Utah.*—The Consolidated Mercur mill treated 282,000 tons of ore, shipped 72,222 oz. gold during the year, and employed an average of 520 men in mine and mill. In Piute County, the Annie Laurie mine on Gold Mountain produced for its owners, the Western Exploration Co., \$401,391, about 20% of which was silver and the balance gold. The cyanide mill treats about 150 tons of ore per day, and 125 men are employed in mine and mill. The Ophir Co., in the State-line district, Iron County, completed its 100-ton mill to treat ore by the Russell process. The mill is equipped with a Gates rotary crusher, a revolving dryer, two 14×26-in. Gates rolls, one 15×36-in. roll, 4 revolving screens, and 2 White & Howell roasters. The engine-room contains a 150-H.P. Corliss engine, a 10-drill air compressor, and an engine for the dynamo which lights the mine and mill; two 80-H.P. boilers furnish steam. The mill was not finished until late in the year, and results are not obtainable. The report of the Horn Silver Mining Co. shows a total shipment of 8,464 tons of ore and 2,766 tons of concentrates during 1901, from which was derived a net revenue of \$206,227. Dividends amounting to \$72,000 were paid and \$87,448 carried forward. The ores contained 3,204 net tons lead, 577,578 lb. copper, 277,382 oz. silver, and 504 oz. gold, besides a large percentage of zinc. Water shortage during the year greatly

hampered the working of both mine and mill. During 1901 the Daly-West Mining Co. milled 57,773 dry tons of ore and 8,798 tons of tailings, producing 12,926 dry tons of concentrates which sold for \$409,591. Shipments of 18,418 dry tons of crude ore, and 733 tons of oxides, realized \$694,221, and \$9,417, respectively, making the total receipts from ore sales \$1,113,229. The net revenue amounted to \$892,489, from which dividends of \$607,500 were paid, and \$13,846 expended in mine and mill construction, with cash carried forward, \$271,143. The total metal content of the ores were copper, 1,326,448 lb.: lead, 7,793 tons; zinc, 5,466 tons; gold, 1,607 oz.; and silver, 1,755,454 oz. The Utah Consolidated Gold Mines, Ltd., which owns the Highland Boy mine, reports for the latter a production for the year of 13,983 oz. gold and 176,331 oz. silver from 167,947 tons of ore treated at the company's smelting and Bessemerizing plant. Besides this amount of ore, 1,651 tons of matte was converted for the Bingham Co., from which was produced 2,931 oz. gold, and 100,068 oz. silver. The total receipts for the year were \$1,944,594 and the total expenses were \$1,312,110, leaving a balance of \$632,484, from which dividends amounting to \$615,975 were paid. In 1901 the Quincy Mining Co. produced from 39,209,925 lb. of dry ore, 984,169 lb. copper, 9,826,007 lb. lead, 1,650,738 oz. silver, and 1,568.4 oz. gold. On April 1, 1902, the Quincy Mining Co. sold its property to the Daly-West Mining Co.

*Virginia.*—The output of gold in 1901 was limited to the placer deposits in Floyd County and amounted to about \$550. Some development work was done on the John's Creek mine in Grayson County and on the Herd mine in Patrick County.

*Washington.*—The production of gold in the State of Washington has been very much restricted for the year, owing to the complete stoppage of operations in the Republic district. The Republic Consolidated Gold Mining Co. suspended operations in June, due to the complicated financial outlook as well as the apparent failure of its veins with depth. The Republic Power & Cyaniding Co. shut down in July owing to insufficient ore supply. While this mill was successful, both metallurgically and financially when running full, operations on a reduced scale were not profitable. A detailed description of the working of this plant will be found elsewhere in this volume under the caption "Review of Progress of the Cyanide Process during 1901." In King County, the Seattle Smelting & Refining Co. has erected a plant for refining silver and gold, particularly Alaska gold dust. The works are at Interbay, Seattle. The California mine of Ferry Co., Republic mining district, made some shipments to the Granby smelter, at Grand Forks, B. C. The ores assay very high in gold and carry some silver and copper. The Silverton mining district of Snohomish Co., developed some activity with the re-building of the Everett & Monte Cristo Railroad, which was washed out and practically destroyed in 1897. Development and assessment work progressed steadily if slowly. The Forty-five mine repaired its 2.5 mile overhead tramway to the railroad. The ore is largely galena, pyrite, and ruby silver in slate. In past years 800 tons of sorted ore have been shipped, but without much profit.

*Wyoming.*—Gold mining has not materially changed during the year. Early last spring there was great activity in the Sweetwater district and several old

properties were opened and considerable ore taken out and crushed. This activity almost ceased with the approach of winter. As usual the Carissa mine was the largest producer. In other localities considerable prospecting was done with indifferent results. In the Medicine Bow Mountains some of the old producers changed hands and new companies expect to commence work during the coming year. The gold production of the State has not increased over the previous year.

#### GOLD AND SILVER MINING IN FOREIGN COUNTRIES DURING 1901.

**NORTH AMERICA.—Canada.**—The larger part of the output of gold in Canada in 1901 came from Yukon territory. According to William T. Robertson, Provincial Mineralogist, the production of British Columbia in 1901 was divided as follows: Placer gold, \$970,100; lode gold, \$4,343,603; a total of \$5,313,703, against \$4,732,105 in 1900. The Ontario mines yielded in 1901, \$244,443 in gold, while in Nova Scotia the production in 1901 was \$604,500.

**British Columbia.**—(By W. M. Brewer.)—The occurrences of free-milling gold ores so far discovered in the Province, have been confined to the Ymir district, near Nelson, Camp McKinney, the Lillooet district near the Fraser river north from the Canadian Pacific railroad, and the Atlin district in the northwestern portion of the Province. It appears somewhat remarkable that notwithstanding the large quantities of placer gold mined from the Fraser river, Granite creek, Thompson river, the Omënica and Cassiar countries in the northern portion of the Province, the discoveries of free-milling gold-bearing quartz have been so few. It is noticeable that a straight line drawn on the map from Granite creek, in the Similkameen country to Douglas Island, Alaska, approximates very closely to the trend of the geological formation or country rock, and that from every prospected stream crossed by the line placer gold has been mined. It would appear from the results of prospecting at various points along this line that a gold-bearing zone with its narrowest portion in the southern part of the Province, maintained continuity the entire distance. Northward of Camp McKinney and Fairview to the Bridge river portion of the Lillooet district, a distance of nearly 300 miles, very little prospecting for gold has been done, and from there to Atlin, except on the Skeena, Naas and Stikene rivers and their tributaries, the country is to all intents and purposes unexplored, although the tributaries of the rivers mentioned yielded good pay from placer mining as early as 1860. The most successful of the free-milling propositions has been the Ymir mines near Nelson, where an 80-stamp mill and a cyanide plant are in operation treating an average of about 200 tons of ore per day, so satisfactorily that this mine ranks among the large dividend payers of the Province, having paid \$200,000 in dividends during the year. The chief feature of interest in 1901 was the cutting through of a large ore body on the fourth level, which is reported to carry \$10 a ton in values. The prospects are very encouraging as to the future development of the mine. The Cariboo, Camp McKinney, has also paid about \$300,000 in dividends, operating with a 20-stamp mill and concentrating tables, the concentrates being shipped to the Greenwood smelter by wagon road.

The Atlin district has been seriously handicapped by the passage of the Alien

production depends largely upon the progress that is made in adopting improved machinery and more economical methods of working. Cheaper transportation is also one of the essential requirements for the future and its importance is recognized by the Dominion Government which has recently mapped out and begun the construction of an extensive system of roads connecting the most important mining creeks with Dawson. It has been stated that the cost of transporting machinery from Dawson to adjacent claims frequently has exceeded by from three to ten times the original cost of the machinery at Vancouver. During the past year some improvements were made in mining methods, more particularly in the wider use of steam apparatus for thawing the frozen gravels, this being done usually by wood fires. Pulsometer pumps were tried for this purpose, and gave such favorable results that they will probably come into more general use. On Hunker creek hydraulicking has been attempted, and a single river dredge has been in operation on Bonanza creek. One of the most important events of the year was the erection of a stamp mill in the vicinity of Dawson which started crushing in November. It is stated that sufficient ore has been mined to keep it running for some time to come.

**Nova Scotia.**—The production of gold during the fiscal year ending September 30, 1901, was 30,537, against 30,399 oz. for the previous year. An unusually dry summer hampered operations in the field, causing some of the mills to close down for several weeks. The Baltimore & Nova Scotia Mining Co. purchased the Guffy-Jennings mine and added a new cyanide plant and a 40-stamp mill to the equipment. The St. Anthony mine, which is located on a vein 8 in. in width, produced 1,289 oz. gold from 1,281 tons of ore.

The Brookfield Mining Co. at North Brookfield during the latter part of 1901 sold its property to a New York syndicate. Its 800-ft. shaft is the deepest in Nova Scotia. The plant comprises a 20-stamp mill and a chlorination plant, and about 70 men are employed. The Fouquoy mine in Moose River district discovered a new ledge of ore nearly 14 ft. in width, the first 56 tons extracted yielded 396 oz. of smelter gold. The Waverly Gold Mining Co. operated its mine successfully during the year. The result of cyaniding tailings with a small plant in the Cariboo district is reported as a return of 330 oz. in gold from 5,495 tons treated, with final clean-up, yielding over \$2 per ton.

The Richardson mine at Goldboro completed during 1901 a railway 10,000 ft. in length, connecting its wharf with the mine. The elevation from wharf to mine is 200 ft. and the motor is a combined traction engine and hoist of 16 H.P. capacity. An addition of 20 stamps to the mill brings the total to 60 stamps milling 120 tons of ore per day. The average yield by amalgamation is \$3 per ton.

**Ontario.**—The Sultana Gold Mining Co. in the Lake of the Woods district during the year operated its 20-stamp mill. The ores milled \$11 in gold per ton. The Ontario Gold Mining & Milling Co. operated the Sakoose mine, which it purchased early in the year, and made shipments from it to the 20-stamp mill at Keewatin, which has a capacity of 50 tons per day. There was a stampede of prospectors to the Sturgeon Lake country during the summer. The Belmont gold mine made regular shipments of bullion, and in October resumed work

on the new dam and power plant which will supply the mine with compressed air as power. The British-Ontario Gold Co., Ltd., organized in London during the latter part of the year with a capitalization of £300,000, has a 99-year lease of the Alice A. mine under an agreement to produce 200 tons of ore per day. The Canadian Goldfields made regular shipments of gold and arsenious oxide during the year.

*Mexico.*—The mining and metallurgical industries of Mexico are well summarized by Dr. Joseph Struthers in the *Engineering and Mining Journal*, October 26, 1901, and a detailed description of mining in most of the States appears in the special issue of that paper of November 30, 1901, which contains a full record of the visit to that country of the American Institute of Mining Engineers. Many individual districts have also been described in the papers of the Institute which were read at the meeting in Mexico in November, 1901. The production of gold in Mexico for 1901 amounted to 499,725 oz. valued at \$10,329,316, as compared with 455,204 oz. valued at \$9,409,063 in 1900. The output of silver for 1901 amounted to 55,150,624 oz. equivalent to \$32,511,293, as compared with 55,804,420 oz. (\$34,269,494) in 1900. There are 11 mints in Mexico which receive gold and silver for coinage. The charge on silver is 4.41% and on gold 4.51% of their respective values, the payment of Government dues or taxes being accepted in any coins in legal circulation. Heavy exportation of silver coins from Mexico to the Orient caused a stringency in the money market during June and July, 1901, which was relieved by the importation of the fine silver from the San Francisco mint. Mexico has the right of way in supplying countries in the far East with silver coinage, which is there accepted as current exchange. The taxes on gold and silver ore are as follows: State and Federal tax, 2.6%; mintage tax, 4.5%; total, 7.1%, based on the gross assay value, to which must be added a stamp tax of 0.6% of the net value. Comparing the net return on a lead-silver-gold ore to the Mexican miner and to the miner of the United States, the latter receives about double that of the former. The mines of Mexico, however, are far less dependent on the market price of silver than those in the United States.

*Chihuahua.*—The smelting plants of the Chihuahua Mining Co. and the Sabinal Mining & Smelting Co. were shut down during 1901 and the ores are sold to the American Smelting & Refining Co., as are also the ores of the Candelaria Mining Co., at Ciudad Juarez. The smelting plant of this last-named company consists of three water-jacketed lead furnaces, one reverberatory roasting furnace, and two English cupelling furnaces. The ores are now shipped to El Paso, Texas, in bond for treatment. Sodium hyposulphite leaching of silver ores is practiced largely in Parral, where the Parral Mining Co. has a 100-ton plant. The crushed ore is roasted with salt at a cost of \$2 per ton of roasted ore, and is concentrated before leaching to avoid difficulty in handling the slimes. A double hearth reverberatory furnace is used for roasting in preference to revolving cylinders on account of the large amount of zinc present in the ores, and supplementary cooling hearths are used to effect a secondary chlorination. At Santa Barbara there are three mills with a combined output of 450 tons, and a new installation of 350-ton capacity is being erected; in addition there are six private

mills in continuous operation, and a smelting plant is proposed to handle the daily production of 330 tons of ore which is shipped from the district. Among the large operators aside from the famous Batopilas mines, are the Hidalgo Mining Co., operating six mines and two mills with an output of 4,000 tons per month, and the Parral Mines Co., Ltd., operating a 400-ton concentrator. The Guggenheim Exploration Co. has a 100-ton mill in operation, and a 400-ton mill under construction. The Parral mining district is a large silver producer, and that the days of bonanzas is not past is proved by the recent strike by a poor peon of a large body of rich silver ore at a moderate depth in the Pamilla mine. The district of Santa Barbara yields gold in excess of silver.

Coahuila.—New smelters are being built which will treat the lead ores from the Sierra Mojada district. Formerly when no duties were collected these ores were hauled by teams to Escalon, and thence shipped to El Paso, Tex., or Argentine, Kan., but to-day as a result of the duties imposed in 1889 and 1896, a large part of the lead ores is treated in Mexico at the smelting works which have been established with American capital. That portion which is shipped to the United States is smelted in bond, and the resultant product sold outside of the country.

Durango.—The Duscubridora copper mine, in Durango, was purchased toward the end of the year for \$2,000,000 by an American syndicate which is also heavily interested in the Mexican Central Railroad. A spur line is to be built from Conejos to Pelayo, a distance of 36 miles, to connect the river with the main line. New smelters were erected and operations on a thoroughly modern basis were inaugurated. Among the more important gold mining companies that have been organized during the year are The Mexican Mining & Smelting Co., capitalized at \$10,000,000 to operate in Durango. This company will erect a smelter at Monterey. The San Fernando mines in the northwestern portion of the State are operated by six turbines, producing 600 H.P. from the Humaya river. The mill equipment comprises a Blake crusher, stamp-mill, reverberatory roasting furnace, hydraulic classifiers, Wilfley concentrators, and canvas tables for the slimes. The smelting plant of the Compañia Minera de Peñoles, near Mapimi, consists of 10 specially constructed water-jacketed furnaces 36×100 in. section at the tuyeres. The hearth slopes to the front, and a separate bullion tap is provided at the side and 6 in. below the level of the slag and matte tap. This construction is made necessary by the strongly basic ores and the large amount of speiss produced.

Guanajuato.—The total production of gold and silver from the famous Veta Madre vein, including the Cardones district and La Luz mine, is estimated at a value of \$1,500,000,000 Mexican. The shafts of the Millado and Rayon mines were first opened in 1588. The patio process, which is in general use in the vicinity, extracts 90% of the silver, 30 to 35% of the gold, and the extraction occupies from three to six weeks' time. It is now giving way to modern methods of milling and stamping.

Hidalgo.—The principal mining companies at present established in Pachuca, are the Real del Monte and Pachuca Mining Co. (the largest one on account of the number of mines in operation and its important management), the Santa

Gertrudis, Maravillas and San Rafael mining companies. Pachuca is pre-eminent among Mexican mining districts because of the variety and amount of machinery, drainage plants, milling plants and its recently inaugurated electric power plants. Its drifts, excavations and cuts represent not less than 300 km. in length. According to a rough calculation, Pachuca since its first discovery has produced not less than 3,500,000 kg. of silver.

Nuevo Leon.—The equipment of the *Compañía Minera Fundora y Afinadora*, at Monterey, consists of 8 steel water-jacketed blast furnaces each 42×120 in. section at the tuyeres, and 12 ft. 2 in. to feed floor; a Pearce turret roasting furnace, two reverberatory roasting furnaces, a liquation furnace, a 40-ton Parkes-process lead refinery and a Moebius electrolytic plant for parting gold and silver bullion.

Sonora.—To the natives of the famous La Cienega dry placers of Sonora is due the introduction to American use of the gold-pan, rocker, and other primitive placer utensils. These famous placers have been desultorily worked for more than 300 years. A recent examination and sampling of these fields yielded results averaging \$1.84 gold per cu. yd., and large tracts assayed more than \$3 gold for the same quantity. The Calera Gold Mining Co., capitalized at \$750,000, has recently been organized to operate in the Magdalena district. The purchasers of the Mulatos gold concession have expended \$150,000 in improvements at the mines and in the erection of a 125-ton stamp mill and a 250-ton cyanide plant. The El Paso-Sonora Mining Co. has been incorporated with a capitalization of \$450,000 to operate gold and silver mines in the Moctezuma mineral belt. The Big Mountain Mining Co., with a capitalization of \$5,000,000 has been organized to operate the historic Las Planchas de Plata mines.

CENTRAL AMERICA.—*Costa Rica*.—The exports of gold and silver from Costa Rica during 1901 amounted in value to \$232,896. The Abengarez Gold Fields, Ltd., operated the Tres Amigos and Tres Hermanos mines during 1901, the reported production being from \$8,000 to \$10,000 per month. Arrangements were perfected by the company for increasing the original equipment of 10 to 40 stamps. The ore is said to carry from \$5 to \$200 in gold and silver, of which 90% is extracted. The Union mine, near Miramar, was idle during the greater part of the year owing to a serious fall that necessitated the opening of new tunnels at lower levels. Stamp milling with amalgamation and subsequent chlorination of the tailings is used at this mine; the ore body averages about \$8 in gold, but is said to be extensive. The mine in the Ciruelitas district owned by the Bella Vista Mining & Milling Co. was taken over by the Thayer Mining & Milling Co., and operations were commenced with 40 stamps. Among the other events of the year were the consolidation of the Sacra Familia, Los Castros, and Aguacate mines under the title of the Aguacate Gold Mining Co., capitalized at \$5,000,000, and the resumption of operations in the Porvenir mine by the Rio Grande Gold Mining Co.

Honduras.—The production of gold and silver for Honduras for the fiscal year ending June 30, 1901, amounted to £10,987 and £114,964, respectively. An increase over the previous fiscal year of £1,985 for gold, and £50,830 for silver. The annual report of the New York & Honduras Rosario Gold Mining Co. for

the fiscal year ending November 30, 1901, says that dividends amounting to \$300,000 (20% on the capital stock of the company) have been paid, which makes the total dividends to date \$1,695,000. The high-grade ore in sight in the mines is estimated at 33,500 tons. The development of the mining industry of this country has been very largely restricted to points easily accessible from the coast, due to the lack of railway facilities, which in great measure resulted from international controversy over the title to the railway concession financed in England some years ago. Aside from the well-established Rosario Mining Co., which produced practically the entire export of bar silver in 1901, other companies have recently met with some success, notably the Aramecina Gold & Silver Mining Co., Ltd., of London, which has found very good ore deposits and exported gold in considerable quantity. The mine is situated near the Pacific coast and the San Salvador frontier. Not far from it the El Trancito mine produces large quantities of low-grade gold ores, which are treated by the cyanide process. E. N. Burke, of Puerto Cortez, Honduras, controls the largest placers in Olancho, and on April 9, 1900, a contract with the Government was closed for Pennsylvania capitalists to establish navigation on the Ulúa and Comayagua rivers, and to build a wagon road from the Comayagua river to the Olancho gold fields, to be followed in 1901 by an electric railway to open communication with the mining districts.

*Salvador.*—The Butter's Salvador Mining Co., recently organized with a capitalization of £150,000 is continuing development work in its gold and silver mines of the Republic.

*Nicaragua.*—The occurrence of gold in parts of Nicaragua was recorded as far back as the 17th century, but it is only recently that there has been any systematic prospecting for and development of payable deposits. The auriferous region is situated some 200 miles from the Caribbean sea coast on the headwaters of the Principulea, Wanks, Was-Puk, Piz-Piz, Tunky and Wawa rivers. The geological formations of the region, according to J. D. Lowry (*Mines and Minerals*, February, 1902) include limestones of Carboniferous age, sandstones, shales and igneous dikes. Quartz veins varying from a few inches to several feet in width are found along the contact of the intrusive rocks and the shales and some of them are now being exploited. From the Constancia mine which is located on a vein 80 ft. in width carrying \$8 to \$10 in gold per ton, about \$150,000 has been taken out in the last four years. The milling equipment of this mine consists of two arrastras. Modern stamp mills have been erected at the Bonanza and Sempre Vivre mines and more will be set up in the near future. The placer deposits are limited in extent, but they sometimes hold rich pockets; a record of 200 oz. of gold has been made by a single rocker working one day. On the whole the conditions for conducting successful mining operations are fairly good; the Nicaraguan mining laws are liberal, labor is plentiful, and the climate, while humid, is not unhealthy. The country however is not supplied with adequate transportation facilities, and commodities of all kinds in the interior consequently bring high prices. Cuicuina, on the Principulea river, and Cuicuinita and Salto Grande are the principal mining towns. The exports of Nicaragua in 1900 included \$310,000 in gold bullion and \$400,000 of gold ore.

**SOUTH AMERICA.—Bolivia.**—The most prominent gold mining companies of Bolivia are the Cheiquiguillo and the Caiconi companies of La Paz, and the North American Co., of the Province of Cerado. There are nine other companies, of which five are English, and four French, at Tipuani. The Tuanani mines are said to yield 4.82 oz. gold per ton. From official calculations based on the valuations of travelers such as A. von Humboldt, it is stated the mines of Bolivia have produced from 1540 to 1750, \$150,000,000 of gold. The second half of the 18th century added \$25,000,000 to this. It is estimated that the silver production of Bolivia from 1545 to 1865 amounted to \$1,500,000; in 1895 to \$13,500,000, and in 1899 to \$6,406,712 only. The diminished output is explained by the depreciated price of silver. The Pulacayo mine owned by the Huanchaca Co. was worked during 1901 under lease, by the American Smelting & Refining Co., the ores being shipped to the company's plant near Antofagasta, Chile, where they were smelted into base lead bullion, or, with copper ore into copper matte.

**Brazil.**—The State of Minas Geraes produces nearly all of the gold accredited to Brazil; alluvial deposits in other parts of the country, particularly on the border of French Guiana yield the remainder of the output. Most prominent among the mines of Minas Geraes are the Morro Velho (St. John del Rey), Passagem (Ouro Preto), Vieira, and Santa Guiteria, all located within the bounds of a small district. During the half year ending August 31, 1901, the Morro Velho mines produced 59,781 oz. gold bullion, equal to 45,309 fine oz. gold valued at \$644,754. The quantity of ore crushed was 77,556 tons of an average yield of \$8.44 per ton. The total costs amounted to \$478,273 while the net proceeds of the half year's operations were \$182,043. This mine has had an eventful history, extending over a period of more than a century, and has been worked by the present company since 1837. The lode which dips at an angle of 45° measures about 600 ft. in length by 45 ft. in width. The mining methods and equipment are modern and well adapted to meet the unusual conditions encountered. Great care has to be exercised in supporting the walls of the mine as disastrous falls have occurred resulting in the entire destruction of the workings and temporary abandonment of the mine. The system of overhead stoping and filling in beneath now used, is successful. The Ouro Preto Gold Mines of Brazil report an output during the year ending June 30, 1901, of 28,581 oz. gold, from which £87,037 was realized. The total expenses in Brazil and London were £82,715, leaving a balance, after including receipts from sale of arsenic and from rents, etc., of £5,107. Additions to the holdings of the company were made with the object of securing the mining rights for the deep levels to be opened in the future. Successful experiments were also carried out to adapt the cyanide process for treatment of the mill tailings. One of the drawbacks to the mining industry of Brazil is the continual fluctuations in the value of the currency which react directly upon the costs of labor, transportation and other items of expense.

**Chile.**—(By W. E. Mathewson.)—Very little silver ore was mined in Chile during 1901, the old bonanzas having been worked out and no new ones discovered. A small amalgamation plant in Iquique operated on ores from the immediate vicinity. The Fundicion Templeman at Antofagasta shipped a few thousand

ounces of bar silver smelted from native ores. The silver produced in copper mattes and base bullion at the Playa Blanca plant was imported from the great Pulacayo mine of the Huanchaca Co., of Bolivia. The Playa Blanca plant consists of 100 stamps, a blast furnace, and nine small cupelling blast furnaces. This plant was purchased by M. Guggenheim's Sons, of New York, in connection with a contract for the output of the Pulacayo mine of the Huanchaca Co., of Bolivia, on lease, the idea being to smelt the lower grade Pulacayo ore with lead furnished by the same mine, and ship the base bullion and high-grade ore to the Guggenheim plant at Perth Amboy, N. J. The company began operations in October, 1899, and continued until December, 1901, when the plant was finally closed down with the exception of a small sampling and shipping agency at Antofagasta. While the first six months of operation were successful financially, the tenor of the lead in the Pulacayo ore deteriorated from 12 to 2%, and sources of lead supply were sought, at first from old Spanish slags from Oruro, Bolivia, later in lead concentrates from Australia and British Columbia. These importations were found to be too expensive to smelt, and early in 1901 the silver ores were matted with the local copper ores, which contained about one-third of the copper in the form of Atacamite, the volatile oxychloride. These ores proved very undesirable for smelting on account of the volatile copper compounds which carried off large quantities of silver as well as copper in the furnace gases. It did not seem wise to build a condensing plant for the fumes under the terms of the lease, and the plant was closed, the ores being shipped to the company's plants in the United States.

*Colombia.*—(By P. N. Ospina.)—There is little to report regarding the progress of the mining industry in the State of Colombia during 1901, except that the civil war kept up its work of ruin and demoralization. The principal mines in Colombia are worked for gold and silver, chiefly the former. Ninety per cent. of the actual production of the country comes from the Department of Antioquia, the most central of the nine departments of the Republic. The value of the bullion exported last year is estimated at about \$3,600,000. There are no statistics regarding ore exports from mines situated less than 20 miles distant from the Magdalena river, which is the principal waterway, but it must have been between 3,000 and 4,000 tons. The ore exported is mainly silver ore, which is shipped chiefly to England and Germany. Notwithstanding the civil war, mining in the interior of the country has been conducted with success. The rate of exchange in the interior (\$1 in gold being worth from \$30 to \$45 in paper currency) has permitted the working of mines that would not pay formerly. Prospecting however has been greatly hampered by the difficulties and dangers incident to the war. Foreigners are usually respected and hospitably treated in Colombia, and have nothing to fear during periods of revolutionary agitation, provided they do not mingle in politics. For this reason mines and camps belonging to foreigners are usually left unmolested. There are two English companies operating in Colombia with most encouraging results, and there is also one French company. American capital is represented by a number of mining camps, generally located on small concessions, and apparently without much means. One of the most interesting mining events of recent years has been the

settlement of the old legal suit about the ownership of the Cruces de Caceres gold and coal fields, probably the most valuable concession of its kind in Colombia. The property is located in the north of Antioquia and is bordered by two rivers, the Nechi and the Cauca, both of which are navigable by steamboats.

*Ecuador.*—The mines in the Zaruma district, Province of Del Oro, are still being successfully worked by the South American Co., of New York. The output of gold for Ecuador for 1901 is reliably estimated at from \$250,000 to \$275,000, against \$200,000 for 1900. A detailed account of the mining industry in Ecuador will be found in THE MINERAL INDUSTRY, Volume IX.

*Guiana.*—The total production of gold in British Guiana during 1901 was 102,258 crude oz. (about 900 fine), as compared with 113,749 crude oz. in 1900, showing a decrease of 11,491 oz., or 10·1% from the production in 1900. The new 20-stamp mill (the first erected in the country) for the Concession Gros Co., of Dutch Guiana, was completed late in the year. The ores are sedimentary, composed of quartz streaks or conglomerates, in clay and kaolin formation. The deposits are covered with vegetable matter and average some 18 in. in depth. One of the deposits of this concession is 36 in. in depth and assays over \$100 per ton; the average of the whole is, however, but \$18 per ton. Gold is well distributed throughout the country, but the climate is very unhealthy, and a number of failures have been made through the erection of recovery plants not suited to the deposits. Rich placer gold diggings in the Inini river district of French Guiana are attracting many prospectors to that locality. During October and November of 1901 over 29,167 crude oz. of gold were brought down to Cayenne, and other lots were expected to follow before the end of the year.

*Peru.*—A Hamburg company, capitalized at \$357,000, has been registered to acquire the property and rights of the Compania Aurifera del Inambari, which has operated to some extent at Poto, in the Sandra district. The largest part of the Cerro de Pasco district silver output, which amounts to 643,000 oz. annually, is obtained by the sodium hyposulphite treatment of the old residues, which contain from 3 to 5 parts of silver per 10,000. The interest in copper in this district has resulted in neglect of the silver mines. The latter are either in bad condition or inundated with water, and at the low prices for silver there is not much inducement to resume work. In January, 1901, a company was formed at Lima, Peru, to drain the inundated mines at Cerro de Pasco. The company is capitalized at 500,000 soles (\$243,500). A United States consular report notes the organization of La Sociedad Nacional de Minería, with headquarters at Lima, Peru, and request is made that a full line of catalogues be sent to the society, to enable them to make recommendations to the Government or other purchasers of machinery of material deemed suitable to Peruvian conditions.

*Uruguay.*—The output of gold in 1900 from the quartz mines of Cunapiru, San Gregorio, and Santa Ernestina amounted to 2,315 oz., valued at \$33,345.

*Venezuela.*—Gold mining during the past two years according to statistics reported by the Custom House has retrograded slightly, yet there is reason to believe that owing to a temporary high tax on the export of gold a large proportion has been taken out of the country by illegitimate means. The Gold Fields of Venezuela, Ltd., a British enterprise, has successfully introduced the cyanide

treatment of mill tailings at its mines in the Yuyuari district, and it is expected that the application of this process will allow the treatment of extensive deposits of low-grade quartz which formerly, owing to the excessive cost of labor and the loss of gold in the mill tailings, could not be worked with profit.

**EUROPE.—Norway.**—The principal silver mines are those belonging to the Government, located at Kongsberg, which have been worked since 1624 with varying success. About 5 tons of silver is the annual output of these mines. Of late a new and very promising lead has been struck. Other silver mines are located at Trollerud, 10 km. north from Kongsberg, at Eidsvold and at Svenningsdal, in Vefsen, Nordland. Silver is otherwise found in many different places, but not in paying quantities. The exports of silver ore in 1899 were valued at about \$1,000.

**Russia.**—(By C. W. Purington).—The mining conditions of Russia so far as reflected in the statistics of production showed some improvement last year. The output in 1901, based on the receipts of the St. Petersburg mint but making a necessary allowance for gold finding outlet by other channels, was 1,253,592 oz. (\$25,911,744), against 1,072,434 oz. (\$22,167,201) in the previous year. Quartz mining and milling in Siberia and eastern Russian has made little progress. In the two districts of Ekaterinburg and Kochkar, of the Ural region, there are at present about 150 stamps dropping and some half dozen mills of the Chilean type in operation. At Kochkar several small cyanide plants for treating tailings have been erected. On the river Reft, about 100 miles N.E. of the city of Ekaterinburg, there is an auriferous slate deposit, from which about \$350 in gold is extracted daily. The ore is treated in a 10-ton Chilean mill. The Chernyladoff Co. owns a similar deposit in the same district which it is working with a 10-stamp mill. The mills in the Ural district are of small capacity and the stamps do not average over 600 lb. each. They are built by Thomas Yates, of Ekaterinburg. Recent operations in the Marinsk district of western Siberia have been very successful, but no complete data as to results are available. Rich finds of gold quartz were made in the summer of 1900, and a 10-stamp mill has been in operation for about one year. The results for 1901 were said to be 6 Russian pounds of gold per day, the Russian pound being about nine-tenths of the avoirdupois pound. The fineness of the gold is not known. In the Achinsk district Mr. C. I. Ivanitsky installed a Krupp 20-stamp mill during the spring of 1900. Ten stamps have been in operation for the better part of two years, the first mill having been partially destroyed by fire. The Fyedorovsky mine, near which the mill is located, has long been operated as a placer, and as such, is practically exhausted. The operations here have yielded about 5 Russian pounds of gold per day from 18 tons of ore, the gold having a fineness of 850. The mill is operated by electric power generated by water. The valley of the Sorela Ooyoos river, in the Achinsk district, about 100 miles south of the Trans-Siberian railway, has recently been the seat of extraordinarily rich quartz finds. The ore is free milling and occurs as a solid quartz reef, averaging 12 ft. in width. The ore thus far encountered runs about \$15 per ton. There are also other large reefs in the same valley, but as yet they have not been exploited. On the Onon river, in East Siberia, S.E. of the Irkutsk, large deposits of low-

grade ore are worked by different Russian companies, the largest property being owned by the Messrs. Sabachnikoff. The mills in operation in this district are of small capacity and poorly constructed. Near Urga, in Mongolia, an American company has installed a 10-stamp mill which was operated during last year. Little has been done so far toward developing the quartz mining industry in Siberia, especially in dealing with refractory ores. All of the districts mentioned above produce gold from free milling ores only. In the Urals a few reduction plants for treating refractory gold ores, have been erected.

*Spain.*—There is some prospect that gold mining will be resumed on an extensive scale in this country after a long period of decline during which the output has dwindled to a few hundred ounces a year. In the district of Corunna, alluvial concessions have been taken up by three foreign companies, and a quartz deposit is to be exploited by the Sagasta Gold Mines, Ltd., of Glasgow. Several mining concessions covering properties in the Province of Leon have also been granted. El Oro Español, capitalized at 2,000,000 pesetas, has started operations on the auriferous mining properties on the Duerna river and many new mining concessions have been registered to work auriferous properties in the Leon province. The principal alluvial concessions in the Corunna districts have been taken up by the Société Anonyme, of Brussels, with a capital of \$300,000; the Valdeorras Gold Mining Co., and the Valdeorras Alluvial Gold Mining Co., of London. The gravel or sand contains 1 oz. gold per cu.m., which is reported to be extractable at a working cost of 10c. There is a group of quartz mines 30 miles from Corunna operated by the Sagasta Gold Mines, Ltd., of Glasgow; the lode averages 18 dwt. gold to the ton, and a cyanide plant has been erected. As a large part of the gold is contained in pyrites, a concentration plant is contemplated. The mines belonging to the company are the Sagasta, Alfonso, Maria Christina, Linares Rivas, and the Pretoria.

*United Kingdom.*—The report of the St. David's Gold & Copper Mines, Ltd., for 1901, showed an output of gold bullion and concentrates valued at £20,254, equivalent to 4,772 fine oz., which was obtained from 15,517 tons of ore. The net profits of the year's operations were £6,563. An additional 20-stamp battery was erected which, with the improvements to the concentrating plant, will doubtless lead to an increased production in 1902. Some gold was also obtained at West Seton in the Camborne district by a company which treated old mine dumps. The total output of gold in the United Kingdom during 1900 was \$253,747.

*AFRICA.—Abyssinia.*—There is much discrepancy in the estimates of different authorities as to gold output of Abyssinia. According to the Diplomatic and Consular Reports of the United Kingdom, the annual export from Addis Abbaba and Harrar is about \$650,000. This amount is probably too high. French authorities state that the annual sales by natives are about 10,000 oz., and upon this basis the total product may be estimated at 20,000 oz. as a maximum limit.

*Egypt.*—Recent exploration in the desert region between the Nile and the Red Sea has shown the existence of ancient gold mines that were once worked on an extensive scale. The Egyptian Mines Exploration Co. during 1901 explored the ancient gold mines in the district between the Nile river and the Red

Sea. The Egyptian Development Syndicate during the latter part of the year began operations on the peninsula of Sinai. These companies are operating on large prospecting areas granted them for a time by the Egyptian government, with the right to locate and hold on certain specified terms any mines discovered therein. Early in 1902 the Egypt & Soudan Mining Syndicate will begin operations, and probably others will get permits. Quartz veins discovered by the Egyptian Mines Exploration Co. at Um Rus on the Red Sea about 240 miles south of Suez appear to be of good value, contain but little pyrites, and have been worked in ancient times to a considerable depth. A shaft to a depth of 130 ft. has not yet reached the bottom of the old workings which have exposed a vein for a length of 700 ft., varying from 1 to 3 ft. in width.

*Gold Coast.*—There was less interest manifested on the part of the British public in the flotation of companies to operate on the Gold Coast, and the market quotations for shares of the established companies was on a lower level than that prevailing in 1900. The reaction was due in part to the unfavorable reports of engineers commissioned to investigate the properties and in part to the fact that the results obtained by companies actually engaged in development work fell short of expectations. The general consensus of opinion among mining men familiar with the field indicates that there is a basis on which to build a legitimate and successful mining industry, although the deposits are by no means equal in extent and regularity to the formation of the Transvaal, with which they have been compared. The development of the country must necessarily be slow, owing to the adverse conditions of climate, transportation and labor, which probably exceed in difficulties those found in any other district of the world where lode mining has been carried on successfully. It is stated that under the present conditions no profit can be made from free milling ore carrying less than 1 oz. gold per ton. The Wassau district, containing the banket reef formation, promises to develop some productive mines in the near future. The district is now in communication with the Coast by the Secondi-Tarkwa railroad, and development work has been actively prosecuted at several concessions. At the Adjak-Bippo mine, operated by the Wassau Mining Co., Ltd., the reef was found at a depth of 770 ft., having a thickness of 3.5 ft., and assaying 22 dwt. per ton. In the Prestea district the mines are located on quartz veins, some of which are extensive and carry good values. Operations have been conducted here intermittently for the last 15 years, but on the whole they have been unprofitable. The Prestea Appantoo mine was engaged last year in sinking a main shaft. The company has two mills of 30 stamps and has already crushed about 4,000 tons of ore. At the Broomassie mine, which has been worked for 10 years, there are over 1,000 ft. of tunnels and a 20-stamp mill has been installed. The exports of gold from the Gold Coast in 1900 were 12,774 oz., valued at £51,062; as compared with 14,249 oz. (£51,300) in 1899.

*Ivory Coast.*—The principal events of the year were the granting of a large number of mining concessions and of a banking commission to the Banque de l'Afrique which will operate in this country. Plans were developed also for the construction of a railway 120 miles in length between the Baudama and Comoé rivers passing through the mining district. The gold deposits, according to

J. N. Griffiths, occur as banket reefs in regular conglomerate beds, while the geological formations of the region include sandstone, shale, schist and quartzite, broken through in places by dikes. There are also alluvial deposits that could be worked advantageously with steam dredges.

*Madagascar.*—The output of gold in 1900, as estimated from statistics of exports, was \$608,000 against \$228,622 in 1899. Nearly one-half of the output in 1900 came from the new gold fields in the Ampassary country. No quartz ores have been worked as yet, although they have been discovered in several localities, the entire product being washed from alluvial deposits, mostly in the native wooden pan. Discoveries of placers have been made recently in the eastern part of the island near the port of Manangary, which, while not as rich as those of Ampassary, are said to be more extensive.

*Portuguese East Africa.*—Discoveries of gold in the Sasa country were reported during the year, but they have not been confirmed by credible authority. The locality is in the Yuanatsi district near the Transvaal border.

*Rhodesia.*—The production of gold in 1901 was 148,753 fine oz., valued at \$3,074,730, an increase of 69,399 oz. or \$1,434,479 over the output of the preceding year. There has been a steady development of the gold mining industry since the native rebellion was quelled in 1897, although the Boer war and the insufficient supply of skilled labor have been serious drawbacks to progress. Efforts were made last year to partially supplant the Kaffirs, who are unsatisfactory workmen, with natives imported from other parts of the country and with Arabs, but the results did not justify a continuation of the experiment. It is possible that the only solution of the question will be found in the introduction of laborers from other British Colonies or from China. With the development of the coal fields now under way, a supply of good fuel will be made available, much to the benefit of the mines, which at present are compelled to rely upon native wood. A company known as the Ayrshire Gold Mine & Lomagunda Railway Co., Ltd., has been formed to work the Ayrshire mine in Mashonaland and to construct a railway from Salisbury to the mine. The share capital is £400,000, of which £100,000 will be held in reserve. A further working capital of £250,000 is to be raised by the issuance of bonds bearing interest at 5.5% guaranteed by the British South Africa Co. and the Rhodesia Exploration & Development Co., Ltd.

*Transvaal.*—Although the Rand district has remained in possession of the British army since May, 1900, little progress has been made in re-opening the mines and starting the mills. A few companies resumed operations on a small scale in May, 1901, and the number was gradually increased until near the close of the year there were 11 mines partially operated, with a total of about 600 stamps, as compared with an average of 5.762 stamps operative during 1899. The output for 1901 was 238,991 oz., valued at \$4,939,944, against 348,760 oz. (\$7,208,869) in 1900 and 3,529,826 oz. (\$72,961,501) in 1899. Dividends paid during 1901 amounted to £415,812, which corresponds to 20s. 2d. per ton milled. It is probable that the output will steadily increase from now on until all of the mines are again in full operation when the productive rate will probably be above \$100,000,000 per year. During the enforcement of martial law

the South African Republic, the Rand district was completely under its control. Twelve of the larger mines were operated and gold to the value of about 1,000,000 extracted which was appropriated by the Government. The direct expenses sustained by the companies during this period, though considerable, were less than had been expected, as very little wilful damage was done by the Boers. The principal item was the cost of maintenance and pumping, amounting to only \$10,000,000, while the total may be placed at about twice that figure. These estimates must be largely increased to include the entire losses sustained during the long period of inactivity and the re-opening of the mines. One of the chief difficulties encountered since the resumption of operations has been the inadequate supply of native labor. The Kaffir workmen who were dispersed during the war have not returned in sufficient numbers, and under the present conditions, which do not permit the former freedom in dealing with the natives, there is no immediate remedy available. During the past four years the scale of wages for mine laborers has been frequently reduced by wide margins, and the natives, especially the more competent class, do not take kindly to this treatment. A proposal was made by Mr. Cecil Rhodes to import Chinese and Indian coolies for the Chartered Company's mines, but so much opposition developed that the plan had to be abandoned; it is probable that such a proposal would be received in a similar spirit on the Rand. An event having an important bearing on the future development of the district was the striking of the gold reef series of the Turf Club bore-hole south of Johannesburg at a depth of almost 5,000 ft. In the main reef the ore body was proved through 45 in. with an assay value of 8.44 dwt. The richest portion being 25 dwt. over a section of 10 in. The second reef showed a thickness of 43 in. assaying 10.6 dwt. with a maximum of 15 dwt. over 9 in. The results are highly satisfactory, indicating the extent of the ore bodies over a large area. To what depth mining can be carried on in the Transvaal is a problem of great importance, upon which directly depends the future of the mines. According to Mr. John Hays Hammond there are no factors operating against mining to a depth of 8,000 ft. vertically, except the additional cost of haulage, pumping and ventilation, which will not be prohibitive. As the increment of temperature is exceptionally small, amounting to 1°F. for each 100 ft. in depth, no difficulty is expected from this source. Another prominent engineer, basing his conclusions upon the temperature factor, is of the opinion that the reefs can be worked down to 12,000 ft. vertically. While there is no certainty what the ultimate limit will be, it is evident that mining can be carried to much lower depths than have been attained thus far in any mining district of the world. As to the output of the district, it has been estimated that the reefs will yield about \$50,000,000 for every mile on the strike and 1,000 ft. on the dip. This estimate is regarded as conservative by Mr. Hammond, who values the available gold in the ore lying within the practicable mining depth of 6,000 ft. at about \$3,000,000,000. This figure must be increased by 100,000,000, according to Messrs. Hatch and Chalmers, to include the gold content of the east and west portions of the Rand. As to the duration of mining on the Rand, Mr. Hammond has expressed the following view: . . . "the policy is to exploit the auriferous areas as rapidly as possible and engineering

methods are all adopted with that end in view. If the exploitation of the deeper levels is not delayed pending the proving of the ground lying above, but is carried on concurrently with the exploitations of the higher horizons of the reefs, the industrial life of the district will, of course, be correspondingly shortened. The working of lower grade ores, made possible by improved economic conditions or other circumstances, would tend to increased longevity of the industry. But were I called upon to express an opinion, I would estimate the future duration of profitable operations on a large scale in the district, at ~~less~~ rather than more than 25 years." The following data give the relative working costs for some of the leading Transvaal mines in 1898: White labor, 31.22%; native labor (including food), 29.83%; explosives (dynamite, fuses, caps), 9.70%; coal, 9.07%; chemicals (cyanides, etc.), 3.22%; tools, steel, shoes, dies, etc., 3.29%; mining timbers, lumber, 4.05%; candles, lighting, 1.38%; sundries, 8.24%; total, 100%.

**ASIA.—Borneo.**—In British Borneo, which comprises the northerly portion of the island, the principal gold mining operations are conducted by the Borneo Co., Ltd., at Bau and Bidi. The company has two cyanide plants disposing of about 16,000 tons monthly and is contemplating the erection of a third plant. Chinese labor is largely employed and the mining costs are low. The exports of gold from this part of Borneo in 1900 were 19,873 fine oz. valued at \$410,038. A review of the gold mining industry in Dutch Borneo will be found under Dutch East Indies.

**China.**—The unsettled condition of affairs in China incident to the native uprising against foreigners has greatly hampered mining operations, especially in the northern part of the country where the principal gold fields are located. The output in 1900, according to estimates based upon the most reliable authorities, was about \$4,300,000. No information is available as to the production last year, but it may be safely assumed that the amount did not exceed \$3,000,000 and probably fell short of this sum. The present outlook for the industry is more encouraging than for several years past; the policy of the Government in granting liberal mining concessions to foreigners should attract capital and offer a more permanent basis for mining enterprises than has been possible under the conditions that have prevailed heretofore. Auguste Mathez, in *Mines and Minerals*, April, 1901, gives a description of an exploration trip in northern China in June, 1900, covering a concession in the district Chai-luh about 100 miles north of Peking. The values of gold, silver and copper were mainly contained in white quartz; in one instance only was the vein filling felsitic. The deepest mine visited was 120 ft., a depth beyond which it was impossible to go with the primitive method of mining pursued on account of the water filling the vein. No powder was used for blasting, the rock being detached by the old Roman method of first heating the rock and then throwing cold water on it. Other mines were examined which showed free gold at the surface running into sulphurets a short distance below and in one instance the ore was of chalcopryrite, the vein measuring 18 in. in the deepest level and averaged 20% copper with 3.5 oz. gold and 10 oz. silver per ton; generally the gold values were much less than this and averaged from \$2 to \$20 per ton. The miners work in inde-

pendent sets, and it is quite common to find a number of pits strung along a vein with only a few feet of ground separating them. The ore is crushed in roller mills similar to a Chilean mill and the pulp shoveled onto an inclined board 4×2.5 ft. held at a slight inclination on the lap of the operator and washed by water thrown on by a boy. The concentrates were worked back with a small rake until of satisfactory condition and the product then panned by hand to extract the gold, the silver and copper contents being lost. A deposit on the borders of Manchuria was examined and while the veins were similar to those in the Chai-luh district, they were of very low grade. The placer mines at Pa-kau were examined also. The mining has been done in a very crude manner, the ground being worked out by innumerable pits to the bed rock, beginning at the top instead of at the bottom of the gulch. All of the excavated material was panned by hand, giving employment to thousands of people.

*Dutch East Indies.*—Some progress has been made in the exploration of the gold resources of Celebes, where several companies are operating under concessions from the Dutch Government, and the mining industry has gained a foothold in Borneo and Sumatra. According to S. J. Truscott, in a paper read before the Institute of Mining and Metallurgy, November, 1901, nearly 100 exploration companies have been formed during the last five years to operate in these fields. In Sumatra the Redjang Lebong mine situated some distance from the coast town of Bencoolen is the principal mining center. This mine was opened in 1898 upon a reef 1,000 ft. in length and 17 ft. in width. Since that time a 40-stamp battery and cyanide plant have been erected and work actively prosecuted. The ore is a close-grained amorphous silica carrying finely disseminated gold in the free state and also as auriferous silver in the proportion of one of gold to 10 of silver. Up to the end of 1900, with an average run of from 10 to 20 stamps the operating results were: ore crushed, 12,072 tons; fine gold produced, 11,308 oz.; fine silver produced, 73,493 oz. In addition there was an accumulation of 2,423 tons of slimes which it is estimated will yield 3,876 oz. gold and 24,230 oz. silver, increasing the total extraction to 25.1 dwt. gold and 8.1 oz. silver per ton, or 85 and 67% respectively of the assay values. The output in 1901 showed a large increase over previous years. About five miles west of this mine is located the Lebong Soelit deposit with an indicated length of 2,000 ft., a width of 8 ft. and an average tenor in gold of about 20 dwt. A tramway has been constructed from the mine to a river that is navigable for light-draft boats to the coast. In the central part of the island around Fort Kock and Soepajang there are also auriferous areas but no veins of value have thus far been discovered. Dutch Borneo contains three auriferous districts: in West Borneo around Sambas, in Central Borneo at the sources of the Kahajang and Kapuas rivers, and in the southeastern portion of the island. A large amount of exploiting work has been done in West Borneo recently with a view of locating the sources of the gold found in alluvial deposits. The results so far have not been very successful, as such veins as were encountered showed little persistency in depth. However, there are large areas of alluvial ground which may be made the basis of profitable exploitation. Central Borneo contains the Kahajang mine, located some 200 miles from the coast, near a stream of that name. A

20-stamp mill has been erected and ore is being taken from two quartz reefs, of which the larger is 3.5 ft. in width and carries 1 oz. gold and 12 oz. silver per ton, while the smaller is about 1 ft. in width and has an assay value of 5 oz. gold or more per ton. Trial crushings with amalgamation gave a recovery of 260 oz. bullion from 139 tons of ore. A third quartz reef 8 ft. in width and carrying about 0.5 oz. of gold occurs in the vicinity of the mine, and a fourth at a distance of about five miles has been prospected with good results. The country rock consists of granites and slates, both of which are traversed by the quartz reefs and by dikes of andesite. Gold is also obtained from alluvial washings in numerous localities. The deposits in southeastern Borneo consist of placers, but there are indications that gold occurs also in the igneous country rock. In Celebes the gold bearing area is confined to the northern part where are located the mining camps of Palehleh, Soemalata, Denerki Bay, Totok and Kotaboenon. At Palehleh, the Nederland Indische Gold Mining Co. is operating on a reef composed of quartz veins and stringers that carries free gold and sulphides. The average width of payable reef is about 6 ft. and the gold tenor varies from 6 dwt. to 4.5 oz. per ton. The poorer grade of ore is crushed in a 30-stamp battery and then pulp passed over amalgamated plates which save 58% of the assay value and then over blanket tables where another 15% is recovered. After this the tailings are concentrated on Frue vanners, which effect a final saving of 11%. Ore of the richer grade is shipped at present to Europe, but the company is planning to erect a smelting plant at the mine for its treatment. Soemalata lies about 40 miles west of Palehleh on the coast. The ore consists almost entirely of sulphides and occurs in a vertical vein breaking through andesite. The coarse ore as it comes from the mine is hand-sorted and passed directly to the smelter bin, while the fines are run through rotary sieves and sized into three products, of which the two finer are jigged and the coarser hand-sorted. This treatment of the fines brings the tenor up to that of the coarse ore which is about 30 dwt. gold and 4 oz. silver per ton. The material containing 50% Fe., 30% S, and 1% Cu is smelted with coral and wood, resulting in a concentration of four of ore into one of matte. The matte is sold in Europe. At Totok the gold occurs in a free state in a quartz gangue. A 20-stamp battery has been set up, and a crushing of 400 tons with amalgamation alone returned 5 dwt. 8 gr. gold per ton. Trial crushings of ore occurring at Kotaboenon have been made which gave a recovery of 5.6 dwt. gold and 15.2 dwt. silver per ton. The mining areas of the Dutch East Indies are thinly populated and labor for the mines must be imported. Chinese and Javanese coolies are usually employed, the former giving better satisfaction. The right of exploration for minerals is granted to such persons or companies as are domiciled in Holland or its East Indian colonies upon application to the Government. This right holds for a term of three or five years on an area not exceeding 52,500 acres in extent, for which an annual rental of about 4c. an acre must be paid. If payable ore be discovered, the holder of the prospecting right, or "*vergunnung*," upon complying with the stipulations of the law as to domicile and financial responsibility, may receive a concession for exploitation. Concessions are granted for periods of 75 years, during which payments must be made to the

Government of 2.5% of the yearly output of mineral and of 40c. per acre of area conceded. The climate of the gold districts is tropical, but if proper precautions are taken it is not especially formidable.

*French Asia.*—This French colony is comprised of Cochin China, and the protectorates of Annam, Tonkin, Cambodia, Laos, the mountainous region between Annam and Laos, and the territory of Kouang-Tchéou-Ouan. The total area of territory is estimated at 630,000 sq. km., and supports a population of 20,000,000. Gold appears to be distributed over much of the country both in quartz and alluvial deposits. The series of veins and alluvial deposits of Quang Nam in the province of Annam appear to be the most important, and have been worked on a comparatively large scale by the ancients. The mines at Bong Miû have been recently operated by the Société des Mines des Bong Miû, and a 30-ton mill has been installed which has given good results in gold recovery.

*India.*—The Colar field produced 504,348 crude oz. of gold in 1901, an increase of 9,318 oz. for the year. In addition there was a small output in Nizam's Territory, Burma, and Madras, which brought the total for India in that year up to 455,871 oz. (\$9,422,855) as compared with 448,100 oz. (\$9,262,226) in 1900. The largest mines are the Mysore and Champion Reef of the Colar field with an annual output of more than 150,000 oz. each, and the Ooregum, Nundydroog and Balaghat mines in the same district with a combined product approximating the same figure. The report of the Champion Reef Gold Mining Co. for the fiscal year ending September 30, 1901, shows an income from the sale of gold of £603,792 and a total income, after deducting royalty to the Government, of £576,329. The expenditures amounted to £242,817, leaving a net balance with the amount carried forward from the previous year of £335,451, out of which £334,359 in dividends were paid. The average yield of ore milled was 1 oz. 4 dwt. 11 gr. per ton, a falling off of about 6 dwt. per ton from the previous year's average. A new cyanide plant and mill were placed in operation which it is expected will maintain the output of the mines at a high rate, even if the tenor of the ore in gold should continue to be low. Discoveries of ore carrying good values were made in the deeper levels opened during the year. The Mysore Gold Mining Company, Ltd., during 1901 treated 127,070 tons of quartz, which yielded by amalgamation 147,354 oz. of gold. From the cyanide works and slags a further 17,227 oz. were obtained making the total extraction 164,581 oz. The sum of £641,977 was realized from sales of gold, yielding a net amount of £610,165, after deduction of royalties. The total net receipts were £614,167 and the expenses were £239,802, so that the net profit for the year's operations was £374,365. The sum of £376,911 was appropriated for dividends, leaving a balance of £1,410 to be carried forward to the account of the following year. The dividends were at the rate of 130% on the share capital of £265,000. The quantity of ore treated was 10,494 tons more than in the previous year, while the increased output of gold was 4,486 oz. From the cyanide works the amount of gold obtained was 2,988 oz. less than in 1900, so that the gain in the year's output was 1,448 oz. The total return of 164,581 ounces was a record for the mines. A large amount of development work was performed, and the estimates show that at the close of 1901 the ore

reserves were about 340,000, or practically a three years' supply for the mills. Successful negotiations were carried on with the Mysore Government for a renewal of the leases under which the company is working; according to the terms agreed upon, the Government is to receive a royalty of 5% of the value of the gold extracted and a payment of 2.5% on dividends distributed after March 22, 1910. The Nundydroog Co., Ltd., during 1901 produced 56,997 oz. gold from 52,030 tons of ore and 60,216 tons of tailings. The available profits of the year's operations were £105,193. In the same period the Ooregum Gold Mining Co., Ltd., recovered 86,918 oz. of gold, from which a profit of £157,472 was realized.

*Japan.*—The output of gold in 1900, according to official sources, was 2,130 kg., equivalent to 68,482 oz. or \$1,415,523. The increase over the preceding year, which amounted to about \$300,000, was due chiefly to the working of the new placer deposits in northern Jesso. Some gold was mined in Formosa in the vicinity of Kelung.

*Korea.*—The gold resources of this country are being rapidly developed under the direction of foreign companies who have received large concessions of gold-bearing territory from the Government. One of the most important concerns operating at present, the Oriental Consolidated Mining Co., of Woonsan, backed by American capital, is operating a grant of quartz and placer land. The company owns the mining rights in a district some 25 by 30 miles in extent which is said to be the richest known gold region in Korea. Two cyanide plants have been erected for treating the tailings from the stamps, of which there are two installations of 20 stamps and two of 40 stamps. The mining staff comprises about 70 foreigners as officials. The 3,000 native laborers are paid from 15 to 25c. per day, the highest wages ever paid in Korea. The British concessions extend over the Unsan district in the vicinity of the region occupied by the American company. At the Gwendoline mine development work was continued throughout the year on a quartz reef carrying pyrites and gold. A part of the mining equipment was set up and crushing will probably begin early in 1902. The mine is reached by 11 miles of roadway extending from Ko Hol on the Hoo Gin river, whence communication is had by water with Chinnampo. The company employs about 15 foreigners and 700 natives. Extensive coal beds have been discovered at Tensan, 10 miles north of the Gwendoline mine. A German syndicate was engaged in prospecting for gold at Tangokae, with 12 foreigners and 500 Koreans on its staff, and a new concession was granted to a French subject covering territory as yet undefined. Some work was done on the Japanese district south of Seoul, but the Russian concession has been but little explored. The exports of gold from Korea in 1900 were 3,633,050 yen, or about \$1,816,525, against 2,933,382 yen (\$1,466,691) in 1899.

*Malay Peninsula.*—The Australian Raub Gold Mining Co. has been operating mines in Pahang for some time, through its two subsidiary companies, the Punjom Gold Mining Co. and the Kechau Gold Mining Co. The parent company owns a 60-stamp Australian mill, which is equipped with electric power. It is reported that the ores range from 7 to 8 dwt. gold per ton on the average with occasional rich patches, and that the expenses of mining and milling are about 15s. per ton.

In Negri Sembilan the Chindras Co. is operating a property of 50 acres and erecting a 15-stamp mill. The Taong gold mine recently financed in London is reported to have an ore body averaging 9 ft. wide, and assaying from 4 to 30 dwt. of gold per ton. The Kedana Gold Mining Co. in Johore is developing a lode carrying arsenical pyrites and some 14 dwt. gold per long ton. Old alluvial workings are reported on the rivers Sungeis Tenoh, Ayer Terap, and Anak Kadana. The deposits of Johore are not more than 30 miles from navigation.

*Philippine Islands.*—The island of Mindanao has been for many years the seat of desultory mining for gold, but the output has been irregular and very limited in amount. In the Pigholugan region the deposits consist of quartz veins in a soft argillaceous slate with bedding planes inclined at a high angle from the horizontal. The veins range up to 4 in. in width and occur in three sets, two of which are vertical and cross each other nearly at right angles, while the third is conformable to the stratification of the slate. The natives in exploiting the deposits excavate deep trenches on the course of the main veins and then dig shallow shafts at the points of intersection which seem to contain the best gold values. According to J. Clayton Nichols, in a paper read before the American Institute of Mining Engineers, November 19, 1901, as much as \$4,000 has been taken from a single hole, yet the deposits are unsuited for operation by large corporations on account of their small size. The region is several miles in extent, and nearly all of it is public domain. Another gold locality that has been exploited by the natives lies about 10 miles west of the port of Surigao. The gold is found in loose surface material which bears evidence of being disintegrated serpentine.

*AUSTRALASIA.*—The production of gold in Australasia during 1901 amounted to 3,724,996 fine oz., as compared with 3,569,844 fine oz. in 1900, an increase of 155,152 fine oz. Western Australia and New Zealand alone show increased yields of gold, the remaining States recording declines, principally due to the extended drought which greatly restricted mining operations. It is interesting to note that the Australian mining journals have departed from their former practice of reporting the gold yield in crude ounces, and now use fine ounces, which is in conformity with the world's standard for such statistics. The percentage of fine gold contained in the crude bullion obtained from the various Australasian mines differed so greatly in amount that a lengthy process of translation from crude to fine ounces is now avoided. The general success of the sulphide reduction processes for the gold telluride ores of the Kalgoorlie

PRODUCTION OF GOLD IN AUSTRALASIA.

(a) Including 18,028 oz. from the Northern Territory.

mining district, accounts in great measure for the increased gold yield of Australasia, and as these plants are being rapidly installed it may be safely predicted that the year 1902 will show a still greater gold production than that of 1901.

*New South Wales.*—The production of gold for the year 1901 was 216,874 oz., valued at \$4,482,785, as against 281,207 fine oz., worth \$5,812,539 during 1900. This decrease was due to the general drought and the business and financial depression, the first crippling operations of existing mines, and the second preventing the opening and development of new mines. In Wyalong a number of mining leases were consolidated, and a company is being organized to operate them which is to be capitalized at £130,000, of which £40,000 will be expended in sinking on the reef. The ore exposed in the Messrs. Neeld's mine, at Wyalong, is valued at £500,000 and the ore on the surface is estimated to contain £40,000 of gold; crushing operations continue to yield satisfactory returns. At the Baker's Creek mine, at Hillgrove, the last clean up returned the following: 750 tons of ore yielded 710·15 oz. of box gold, and 474·65 oz. of plate gold, a total of smelted gold of 1,175·8 oz. The Christmas Gift gold mine at Cullinga, 12 miles southeast of Cootamundra, returned from 2,500 tons of ore crushed last year, 1,627 oz. gold saved by amalgamation, and about 500 oz. recovered by smelting with copper ores or recovered from concentrates by cyaniding. The Dawn of Hope mine, on the same reef as the Christmas Gift, has opened and exposed a large body of low-grade ore, and the management is now sinking deeper in the hope of encountering shoots of richer ore. Several gold prospects of Cullinga yield 0·3 oz. per ton and the reefs are large, but capital is lacking to treat them on the large scale necessary with such a low return. The Burdett-Coutts mine, at Canowindra, which has been worked by different managements for the past 10 years without much profit to the stockholders, has a main shaft 500 ft. in depth, and a winze sunk from the 500-ft. level for another 100 ft. The 500-ft. level has been driven on the vein for a distance of 420 ft. without a break, and the value of the ore has never been less than 1 oz. gold per ton. In the Gundagai mining district a new auriferous section has been opened above the famous old Jackalass alluvial lead. Some miners, while tracing the source of alluvial gold, found a quartz reef about 12 in. wide in a country of slate and serpentine. The find is in the ranges about 6 miles southeast of Gundagai and yields about 3 oz. gold per ton. The report of the Broken Hill Block 14 Co., of New South Wales, notes that the substitution of briquetting and desulphurizing methods for their former roast processes has resulted in considerable economy. Three smelting furnaces are now doing the work that required five by the old method. The average grade of ore sent to the mill was Pb 16·7%, Zn, 12·4%, and silver 10·9 oz. per ton. The cost of treating the concentrates and slimes by briquetting proved to be one-half of the former cost of roasting. The company reports a total reduction of liquid assets of £9,559 for the half year ending September 30, 1901, due to reduction in the value of bullion and ore carried over from the previous half year, a considerable outlay at the smelting works, and the cost of development work at the mine.

*New Zealand.*—The gold production of this colony is showing an upward

rend which promises to attain in the near future the high water mark of the early days when the output was over \$10,000,000 annually. In 1901 the production was 412,189 fine oz., valued at \$8,519,947, against 338,902 fine oz. (\$7,005,103) in 1900. The favorable condition of the industry is due to the successful working of medium grade ores and to the extended operations of the gold dredge. This appliance has been found very economical for working alluvial gravels, and a considerable portion of the total output of gold is now mined by this means, the amount recovered in 1901 being 65,531 oz. Otago and Westland are the principal alluvial districts, the former being the more important and containing the Kawarau and Molyneux rivers, the richest gold-bearing streams in the colony. Dredging operations are limited to a period of about six months during the winter season when the streams are at low-water. The number of companies registered is about 300, representing a capital of over \$15,000,000. According to Mr. Raymond Payne<sup>1</sup> the ladder-bucket type of dredge is the one universally adopted, the other types having been found unsatisfactory. The maximum capacity of the buckets is 7 cu. ft. and the range or scope varies from 60 ft. below to 60 ft. above the water line. Recently an American firm, the Quintard Iron Works, of New York City, has secured a contract for the construction of four dredges which are to cost about \$30,000 each and will have a capacity of 13,000 cu. yd. per week. It is estimated that the working capacity of each dredge will be about \$264 per week, or, approximately, 14 oz. of gold, so that if a saving of one grain per cu yd. is made the net earnings will amount to \$216 per week. Some of the dredging enterprises have been very successful from a financial standpoint, as is instanced in the reports of the stock companies, one of which shows a dividend distribution of 862% in two years. The returns from the Hauraki gold fields were very satisfactory, both as regards the older mines and those under development. The Waihi Gold Mining Co., Ltd., during 1900 treated 112,012 tons of ore for a yield of 69,348 oz. gold, 190,555 oz. silver, and 22,964 oz. base bullion, the whole product being valued at £310,316. The average content of the ore, according to assay, was 14 dwt. 5 gr. gold and 3 oz. 4 dwt. 21 gr. silver per ton, a slight reduction in gold as compared with the previous year. The net profits of the year's operations were £172,225 and the dividend distribution was £160,000 or 50% on the capital stock. The report of the Waihi Co. for 1901, shows a profit for the year of £232,480, out of which shareholders have received dividends to the amount of £166,425, being at the rate of 50% per annum. During the year 159,325 tons of ore were treated with a gold yield of £461,205. The gross revenue was £464,810, and the total expenditure £232,330. In examining a large number of sulphide ores of the Hauraki gold fields, Mr. F. B. Allen, in the *Transactions of the Australasian Institute of Mining Engineers*, 1901, found that in no case was the percentage of tellurium present sufficient to indicate in what combination it occurs, although in every ore containing copper, whether in small or large amount, the presence of tellurium was detected. The following analyses of ores containing tellurium were given: Coromandel, containing 25% mispickel, 200 oz. gold, 90 oz. silver per ton and a small percentage of tellurium; Tapu, containing dense iron pyrites

<sup>1</sup> *Engineering and Mining Journal*, Sept. 28, 1901.

and chalcopryrite, 2.25 oz. gold, 250 oz. silver, 7.5 oz. tellurium per ton. Waiomo, Broken Hill mine, 2 oz. gold, 30 oz. silver, and tellurium less than 1% of the bullion. Waiomo, Gem mine, white quartz, 15 oz. gold, 600 oz. silver and 12 oz. tellurium. Other results obtained indicated that tellurium was not present in the auriferous quartz ores in amount sufficient to affect the extraction of the gold. According to reports of the Mines Department the production of silver in New Zealand for the 11 months of 1901, ending November 30, was 466,793 oz., against 278,404 oz. for the corresponding period of 1900. The Department of Mines of New Zealand has offered a reward of £2,000 for the invention before January 1, 1904, of a machine for saving profitably 3d. of gold per cu. yd. contained in the black sands of New Zealand. The invention must differ from known appliances, must be readily transportable, and capable of treating a minimum of 30 cu. yd. per hour, and the patent rights to be inoperative in New Zealand. The plant must be operated for six months to demonstrate its success.

*Queensland.*—The gold production in 1901 was 576,920 fine oz., valued at \$11,924,936, against 676,029 fine oz. (\$13,973,736) in 1900, showing a decrease of 99,109 fine oz. in the year. This unfavorable result was due largely to the exhaustion of tailings heaps undergoing cyanide treatment, especially in the Charters Towers district, and to the severe droughts prevailing in parts of Queensland, which compelled the Mount Morgan Co. to curtail its operations. The outlook for the present year is favorable to an increased yield, but it is doubtful if the figures of 1900 will be attained. The report of the Mount Morgan Gold Mining Co., Ltd., for the year ending May 31, 1901, shows an output of 215,461 tons of ore, from which 173,833 oz. of gold, valued at £693,273, were obtained. The underground workings supplied 58,690 tons of sulphide ore and 14,177 tons of oxidized ore, and the open cuts supplied 149,384 tons of oxidized ore. Dividends amounting to £350,000 were paid and £22,279 was carried over to the following year out of a total income account of £734,867. The average yield per ton of ore was 16.13 dwt., or 0.48 dwt. per ton more than the average yield in 1900. Within the six months ending November 30, 1901, the output from the mine was 111,181 tons of ore containing 82,610 of gold, while the dividends declared were £116,666. The Charters Towers field reported a yield for the year of 204,783 oz. from 214,595 tons ore milled and 157,440 oz. from 381,668 tons sands treated in cyanide works, a total, after including the small amount of gold obtained from smelting and placer operations, of 366,431 oz., as compared with 454,679 in 1900. There was a falling off in the output from cyanide works of 80,495 oz., for which the decreased tonnage treated was accountable. Of the individual producers the Brilliant and St. George Gold Mining Co., the Brilliant Central, and the Day Dawn Block and Wyndham held the most prominent place, paying £156,000 in dividends. Development work was carried out which should have a favorable influence on the future yield of the district. The operations at Glympie were very satisfactory, the output, 111,061 oz. from 112,100 tons of ore being the highest recorded. The dividend distribution was £201,722. The returns from the Croyden field showed a total of 72,593 oz. recovered from 2,677 tons of quartz and 21,513 tons of residues.

*South Australia.*—The production of gold for 1901 was 21,939 fine oz., valued at \$453,472, while the figures for 1900 were 25,713 fine oz. gold, valued at \$531,498, showing a loss for 1901 of \$78,026, which was due in large measure to the drought which was extended and severe over Australasia generally. Most of the gold obtained from South Australia continues to come from the mines owned and operated by the Chinese in the Northern Territory, and of the 1,304 men engaged in mining in 1900 in that part of the country, 1,226 were Chinese.

*Tasmania.*—The gold production for 1901 was 52,627 fine oz., valued at \$1,087,800, showing a decline of 20,951 fine oz. (\$433,057) as compared with the previous year. The largest mine in the colony is the Tasmania Gold Mining & Quartz Crushing Co., in the Beaconsfield district, which, during the year ending September 30, 1901, produced 33,434 oz. gold, valued at £127,157 from 24,640 tons of ore. A marked falling off was noted in the returns for September, which was attributable to the exhaustion of tailings stocks undergoing treatment by the chlorination process. Forty head of stamps are being added to the present battery of 65, nearly doubling the crushing capacity. In the semester closing September 30, 1901, the Mount Lyell Mining & Railway Co. extracted 135,511 tons of ore from its mines, which gave an average assay of 2.35% copper and 2 oz. silver and 0.065 oz. gold per ton. The amount of gold recovered from blister copper was about 10,000 oz. At the New Golden Gate mine in the Mathinna district, new ore bodies were found on the 1,000-ft. and 1,400-ft. levels, and it was decided to extend the main shaft to 1,600 ft. This district is second to the Beaconsfield in importance.

*Victoria.*—The production of gold for the year 1901 was 743,467 fine oz., valued at \$15,367,643 against a production for 1900 of 807,407 crude oz. (760,142 fine oz.) (\$15,712,140), a decrease for the year in value of \$344,617. On January 1, 1901, there were 29,410 men employed in gold mining, and 10 hydraulic dredging plants in operation, while the 103 gold-dredging leases in force occupied but 5,903 acres of the 100,000 acres available for alluvial working in the State. While there are seven mining districts in Victoria, three of them—Ballarat, Bendigo, and Beechworth—produce nearly two-thirds of the total gold yield of the State. The gold recovered from quartz represents 67.2%, and that from alluvial deposits 32.8% of the whole. Victoria has continued its policy of road building, having added over 100 miles during 1900 at the expense of the State.

*Western Australia.*—There was a general improvement in the gold mining industry from the unfavorable conditions prevailing in 1900, and the output showed a large gain. The total yield for 1901, as reported by the Governmental authorities, was 1,700,980 fine oz., valued at \$35,159,257, against 1,414,273 fine oz. (\$29,233,035) in the preceding year, this being the highest figure yet recorded in the history of the Western Australian gold fields. The chief factors contributing to the large increase were the opening of several new mines, the extension of operations by the established enterprises, and the partial solution of the problem of dealing with the low-grade sulphide ores. Some progress was made in lowering the cost of ore treatment by the different companies, although this feature is not reflected in the dividend payments.

which were less than in 1900. The East Coolgardie field as usual held first place in respect of output, the Mount Margaret, Murchison, North Coolgardie, and Coolgardie fields following in the order mentioned. The Lake View Consols, Ltd., reports for the year ending August 31, 1901, show the tonnage treated by the Diehl process, introduced early last year, at 41,054, the product from which was 40,121 oz. in gold bullion, and 1,601 tons of concentrates containing 21,217 oz. gold, which were treated at the Freemantle Smelting Works. The average costs during the time the Diehl process was in operation, without counting realization on concentrates, was 28s. 3d. per ton. In addition 160 tons of oxidized sands and 15,733 tons of oxidized slimes were treated early in the year, with a saving of 43, and 6,793 oz., respectively, which exhausted the supply of this class of material. The total output of gold for 1901 was 121,684 oz., approximately, valued at £461,584, made up as follows: Furnaces, 53,251 oz.; oxidized sands and slimes, 6,836 oz.; Diehl slimes, 40,121 oz.; Diehl concentrates, 21,217 oz.; slags, 259 oz.; total, 121,674 oz. Additions to the plant making a capacity of 12,000 tons of ore per month are contemplated. According to the report of the Great Boulder Perseverance Gold Mining Co., Ltd., in 1901, 108,355 tons of ore and 32,240 tons of tailings were treated, yielding gold valued at £487,733, as compared with £160,368 the previous year, extracted from 42,297 tons of ore, and 25,990 tons of tailings. The costs per ton at the sulphide plant have been reduced from 34s. 11.5d. in 1900, to 24s. 10.5d. in 1901. At the annual meeting of the company it was decided to charge off the whole cost of the plant, £161,390, which allowed £8,224 to be carried forward. In development £31,977 was spent during 1901, against £28,338 for 1900. The main shaft has now reached a depth of 1,000 ft. The Great Boulder Proprietary Mines Co., Ltd., has proved its ore body for a total depth of 1,300 ft., or 200 ft. below sea level, which is the greatest depth thus far attained in Western Australia. During the fiscal year ending August 31, 1901, 54,887 tons of ore was treated, with a saving of 115,909 oz. of gold. An interim report for 1900 shows a net profit of £250,139 during the year, from which sum must be deducted a total taxation of 10% from the English Income and Australian Revenue taxes. The expenditure was greater during the year, owing to the introduction of the new sulphide plant and the larger amount of slimes treated and handled. The Ivanhoe Gold Corporation announced early in 1901 that no dividends would be paid at present, owing to the necessity of holding cash on hand for expenditures in development and to make provision for the installation of a new sulphide plant. In 1900 this company treated 74,750 tons of ore, yielding 107,052 oz. gold, an average of 1.43 oz. per ton treated. The plant of the company includes 61 stamps, 16 leaching vats of a capacity of 80 tons each and 4 filter presses. In 1900 the Golden Horseshoe Estates, Ltd., treated 76,532 tons of ore which yielded 132,863 oz. of gold, an average of 1.73 oz. per ton treated. The equipment of this plant includes 55 stamps, 29 leaching vats of a capacity of 70 tons each, and 9 filter presses. The Pendinnie Gold Mines, Ltd., was organized late in 1900 to take over five leases on an area of 84 acres in the Yerilla district, from the London & Hamburg Gold Recovery Co., Ltd., the owner of the Diehl sulphide process. The Diehl process seems to have scored a decided success in the Kal-

oorlie district, the costs of treatment per ton of ore have been reduced in a number of instances, and familiarity with the details of the process has revealed a few problems for future economies. The percentage of concentrates (10 to 12%) reduced compels a subsequent smelting process, in which gold losses may occur, but in general this process appears to have successfully solved the problem of treating the refractory telluride ores. The successive steps of the Diehl process are: Wet-crushing and amalgamation of free gold; concentration and subsequent separation of the sands and slimes; regrinding the sands until both sands and slimes will pass a 120-mesh screen; agitation of the slimes with bromo-cyanogen; and finally, filter-pressing, to recover the solution. The ores are crushed and amalgamated in stamp batteries, concentrated on the ordinary wet-concentration tables, and the sands are re-ground in tube mills. The lowest cost so far claimed for the process is 21s. per ton of ore treated which of course includes plant management, etc., and the greatest recovery claimed is 97% of the gold content of the ore. A further account of this process will be found under the caption "A Review of Progress in the Cyanide Process during the Year 1901" elsewhere in this volume.

*New Guinea.*—A German company has received a concession for the exploration of a large extent of territory in Kaiser William's Land which is thought to be gold bearing. In British New Guinea there are placer deposits that yield a small amount of gold annually, the export during the fiscal year 1899-1900 amounting to 9,256 oz., valued at \$162,390. On Woodlark Island discoveries of a gold-bearing formation have been made and a 20-stamp mill to treat the ore is now in course of erection.

## PROGRESS IN GOLD MILLING DURING 1901.

BY R. H. RICHARDS.

## GOLD MILLING.

*The Bryan Mill.*<sup>1</sup>—D. W. C. Nelson states that the Bryan mill has saved as much as 75% inside the mill, the principal part of the amalgam collecting in the eddy between the die and the central cone. The mill has an advantage over stamps in that it does not slime the ore, which assists the subsequent concentration. The capacity of the mill is from 5,000 to 8,000 tons of Baker County (Oregon) pyritic ores with one set of wearing parts; and with hard ore a 5-ft. mill will crush in 24 hours as much as ten 850-lb. stamps. With these ores best work was done with the No. 8 slot Russia iron screen.

*Huntington Mills.*<sup>2</sup>—The original form of the Huntington at the North Boulder mill, West Australia, showed a gold yield of about 78%. The capacity of a 5-ft. mill is from 13 to 14 tons per 24 hours; the screens are No. 40 diagonal slot without buhr; the mill makes from 65 to 70 revolutions per minute, uses 700 gal. of water per hour, and is charged with 70 lb. of mercury. At the Great Boulder mill the mercury loss is from 0.425 to 0.470 oz. per ton of ore treated.

*Tremain Steam Stamp.*—Experience shows that a steam stamp of this type in 24 hours will pulverize from 10 to 15 tons of ordinary gold quartz to 40-mesh. The power varies from 7 to 10 H.P., depending upon the speed at which the stamp is run. The water required for the mill and boiler is 800 gal. per hour, or better, 1,000 gal. if sufficient can be had. The screen area is 450 sq. in. as against 475 sq. in. of a battery of five gravity stamps. A recent installation of eight Tremain stamps has been made.<sup>3</sup> A comparison of power and capacity shows a steam stamp mill of eight stamps is equivalent to 40 gravity stamps.

*Prospecting Steam Stamp Mill.*<sup>4</sup>—A mill of three 40-lb. stamps, dropping 250 times per minute, is capable of crushing about 4 tons of quartz per day. The entire outfit complete, with boiler, plates, etc., without the road carriages, weighs about 7,100 lb., and costs about \$1,250. At the Coolgardie Exhibition, in 1899, this mill crushed 50 tons, averaging 4.07 tons per 24 hours; 83.5% of the gold content was saved by amalgamation.

*Snodgrass Pulverizer and Concentrator.*—This apparatus, made by S. K. Snodgrass, Denver, Colo., is used to save gold, and consists of the following parts arranged in series: (1) a horizontal iron trough 26 in. in diameter and 18 ft. long; (2) a revolving screen; (3) a second trough 26 in. in diameter and 12 ft. long. In each trough is a strong revolving shaft to which are attached projecting teeth of white iron arranged spirally, their action being to disintegrate the material and to carry it forward at the same time. The revolutions per minute are from 150 to 250 for the first shaft, and from 300 to 500 for the second. A space of about 4 in. between the ends of the teeth and the bottom of the troughs fills up with sand and gravel, and it is claimed that the free gold settles. The ore fed at the end of the first trough passes through and leaves some of the gold in the

bottom. Thence it falls into the screen and the coarse material is removed and sent to the dump; the fine material undergoes a second treatment in the second trough. The machine has been used successfully in Colorado.

*Foundations.*<sup>5</sup>—It is claimed that a rock foundation is not necessary for stamp mills, as one of concrete has been used successfully. Attention is called to the following points of this style of foundation: (1) the foundation pit should be sufficiently deep to allow the material at the bottom to become homogeneous; (2) allow 25 sq. ft. at the base for five stamps, and 60 sq. ft. for 10 stamps; (3) use best Portland cement and concrete of four parts clean sand, two parts broken granite, one part Portland cement; (4) the concrete foundation should be not less than 30 in. thick; (5) finish off with one part sand and one part cement.

*Battery Construction.*<sup>6</sup>—Mr. C. G. Warnford Lock calls attention to the difficulty encountered in the removal of worn-out mortar boxes caused by the rusting of anchor bolt nuts, and suggests that the anchor bolts, instead of traversing the mortar blocks, should occupy shallow recesses cut in their surface, and should be looped at the lower ends to encircle a short length of 1·5-in. iron pipe which is driven into an auger-hole extending through the blocks from front to back. During five years' wear in a battery with weak foundations and excessive vibration, this anchorage gave entire satisfaction and afforded every facility for mounting and dismantling the boxes; the same principle may be applied to concrete blocks.

*Iron Guides.*—As a result of several years' experiments by Mr. Robert Canning<sup>7</sup> a simple cast-iron box was adopted which was turned true in a lathe and finished with a perfectly smooth wearing face. A guide so made lasted for three years without repairs. The stems never became even warm to the touch, while with wooden guides they were always quite hot; the consumption of lubricant is reduced more than half.

*Power Required by Stamps.*—Mr. A. W. Warwick<sup>8</sup> gives in detail the formulæ necessary for calculating the power required by stamps. Previous formulæ for calculations did not come within 30% of the actual power used, probably because the inertia of the stamp was not considered. By allowing for this factor, results can be obtained which check within 2·5% of the actual power used. Courtenay de Kalb<sup>9</sup> has found that 32% is the average amount of ore, under ordinary working conditions, that passes through a 100-mesh sieve after crushing in a stamp mill. He advocates increased amalgamation inside the mortar and thinks it a good rule not to allow 60% of the amalgamable gold to escape through the screen. The adoption of a positive ratio would seem impossible; if the gold was very coarse, the ratio would come higher than that advised by Mr. de Kalb, and if very fine, it would be impossible to reach.

*Electro-Silvered vs. Plain Copper Plates.*—Mr. Jas. R. Cooper<sup>10</sup> raises the point that Mr. Halse's<sup>11</sup> tests were not convincing because the grade of copper was not

<sup>11</sup> A paper read before the Institution of Mining and Metallurgy, Vol. IX., 1900, p. 155. See also *THE MINERAL INDUSTRY*, Vol. IX., 1901, p. 363.

stated. The chief impurity of commercial copper is oxygen, and it is the belief of Mr. Cooper that a deoxidized copper plate can be made which will be equally as good as a silver-plated copper plate.

In reply, Halse<sup>12</sup> states that while no analysis of the copper plate is available, it was of good quality, being that commercially known as "brazier's copper." The annealing was carefully done, and the whole surface of the plate scoured to bright copper before amalgamating. He thinks that the staining was not due to impurities in the original copper, although he is unable to give positive proof.

*Water Economy.*<sup>13</sup>—This factor is very necessary in stamp milling in the arid districts of the Southwest. The two common methods are the dam and reservoir and the settling tanks; the former will save about 50% of the water, while the latter saves about 85%. A useful device for a coarse concentrating mill is an old jig fitted with a fine screen of coarse wire: all compartments are thrown into one and the plungers are fitted with a simple valve which partially exhausts the air from below the screens; the tailings and water are led to the jig, the water being sucked into the hutch, while the tailings are removed by a screw conveyor to a conveying belt and thence to the tailings pile.

A statement of the amount of water used to mill a ton of ore in different mills is made in the following table. Owing to the varying conditions any comparison will be approximate.

| Name and Locality of Mill. | Capacity per Day. | Method of Saving Water.               | Amount of Water Lost per Ton of Ore. |                              |
|----------------------------|-------------------|---------------------------------------|--------------------------------------|------------------------------|
|                            |                   |                                       | With Saving.                         | Without Saving. (Estimated.) |
|                            | Tons.             |                                       | Gallons.                             | Gallons.                     |

*Lake View 50-Stamp Battery (West Australia).*—According to A. G. Charleston,<sup>14</sup> ore is crushed by a Gates breaker at the shaft, and conveyed by a rope tramway to the mill. The 900-lb. stamps drop 6 in. 90 times per minute, and are fitted with gib tappets; in 1898 the duty per stamp per day was 4 tons. Gold is caught on amalgamated copper plates and canvas tables and the tailings are cyanided. The cost per ton in 1898 was 10s. 1·2d. (\$2·46); and in 1899 it was 6s. 10·463d. (\$1·67).

*The Morro Velho Stamp Mill, Brazil.*<sup>15</sup>—This mill has 120 stamps fitted with double discharge mortars. The stamps weigh 800 lb., and drop 8 in. from 80 to 85 times per minute; 60-mesh corrugated screens are used. The pulp after leaving the amalgamated plate passes to a distributor, thence to straking and automatic washing area. About 80% of the gold is retained on the plates with the richest pyritic sand, which, after further concentration passes to steel amalgamation barrels lined with wood. Each barrel contains 2·7 tons of concentrates which is charged with 50 lb. of mercury and a certain quantity of water; amalgamation is complete in about 12 hours; the extraction averages 70% of the

<sup>12</sup> *Engineering and Mining Journal*, Vol. LXXII., 1901, p. 464.

<sup>13</sup> *Engineering and Mining Journal*, Vol. LXXII., 1901, p. 225.

<sup>14</sup> *Ibid.*, p. 405.

<sup>15</sup> *Engineering and Mining Journal*, Vol. LXXII., 1901, p. 485.

assay value of the ore. The barrels discharge to separators, and the sand goes to the so-called "Oxygen Process," which extracts from 70 to 80% of the remaining gold content.

*Gold Milling Practice at the Athabasca Mine, Nelson, B. C.*<sup>16</sup>—The ore carries free gold closely associated with blende and galena. Ten 980-lb. stamps drop from 5 to 8 in. from 80 to 115 times per minute; the height of discharge is 6.5 to 11.5 in.; a diagonal slot punched screen is used. With new dies a 50-mesh screen is used, after 30 days a 40-mesh, and when dies are well worn down a 30-mesh. This is done because inside amalgamation is desired, the level of discharge being maintained constant and the increased height of discharge is compensated for as the dies wear down. The maximum crushing capacity is 2.33 tons per stamp per day. Inside amalgamation yields from 30 to 45% of the bullion, as against 20% from the outside lip and apron plates. Outside plates are dressed five times every 24 hours, and the amalgam is removed from the apron plate every two days; the lip plates are cleaned and the mortar opened and cleaned of refuse every sixth day; the inside amalgam is removed during the monthly clean-up. The total time lost from monthly clean-ups aggregated eight days and 17 hours in one year. The pulp from the plates is sized in a cone sizer, the coarsest product goes to a 4-ft. corrugated belt vanner, the three other sizes are treated on separate 6-ft. plain belt vanners. The tailings are cyanided.

*Cheap Gold Milling at Chiapas, Mexico.*<sup>17</sup>—The ore is soft and of low grade, averaging in value 0.2 oz. per ton of 2,240 lb. It is crushed in a 10-stamp battery with 750-lb. stamps dropping 5 in. 100 times per minute; a 40-mesh screen is used, and there is no inside amalgamation. The extraction averages 30%, due to the fact that a portion of the gold is covered with iron oxide. The cost of milling is 17.6c. per ton of 2,000 lb., not including power—the whole mill being driven by water power.

*Treatment of Auriferous Mispickel Ores at Deloro, Ontario.*<sup>18</sup>—The ores are generally quartz, more or less heavily impregnated with arsenopyrite, occasionally with copper pyrites and frequently with large percentages of pyrites. At the shaft-house the ore passes to the grizzlies; the oversize is sorted, the white quartz being returned to the mine, where it is used as stope filling, and the remainder, with the undersize, passing to the mill. The stamps are 20 in number, each weighing 850 lb.; the height of discharge is from 6 to 8 in.; 10 old stamps drop from 7 to 8 in. 100 times per minute, and have a capacity of 3 tons per stamp per day; 10 new stamps drop from 6 to 7 in. 110 times per minute, and have a capacity of 4 tons per stamp per day. A 40-mesh buhr slot screen is used, which lasts from 10 to 18 days. Inside amalgamation averages 20% of the assay value in gold. Heavy silver plating, 4 oz. per sq. ft., is best for this ore. Inside and outside amalgamation saves on an average 57% of the assay value. From the old 10 stamps the pulp goes to two corrugated belt vanners, thence to classifiers, the three products of which are treated on smooth belt vanners. The tailings average from 2 to 2.5% of the original gold content, and 0.5% of the original mispickel content of the ore. The pulp from the new 10 stamps passes to two Wilfley tables,

<sup>16</sup> *Journal of the Canadian Mining Institute*, Vol. IV., 1901, p. 83.

<sup>17</sup> *Transactions of the American Institute of Mining Engineers*, Vol. XXX., 1901.

<sup>18</sup> *Journal of the Canadian Mining Institute*, Vol. IV., 1901, p. 113.

thence to a classifier, producing coarse sand, which passes to a Bartlett table, the overflow passes to the three-compartment classifier. All concentrates are treated at the leaching plant by the bromo-cyanide process, and are calcined afterward for the arsenic content.

*Improved Amalgamation Process.*<sup>19</sup>—The object of the process is to increase the percentage of extraction of gold by amalgamation by passing ammoniated air, mixed with either chlorine or bromine into the wet pulp. A number of tests have been made at the testing works of Henry E. Wood, Denver, Colo., and in all cases an increase in the amount of gold extracted by amalgamation was obtained. At a test made at the Anderson mill at Idaho Springs, Colo., with gold ore containing \$10 per ton, the ordinary tailings showed a value of \$4 gold per ton, while the tailings of the ore treated with ammonia gas showed a value of \$1.80 per ton. It is presumed that Mr. Wood has obtained his results by weighing the increased bullion obtained and not by the assay of tailings. Otherwise the gain might not be proved.

*Crown Mountain Mill, Georgia.*<sup>20</sup>—At this mill four giants are used for breaking down saprolite carrying free gold. The detritus from hydraulicking along with the broken ore from vein mining is transported to the mill by a sluice which in one place is cut, the continuing section being dropped 4 ft.; grizzlies with 0.75-in. spaces are introduced at this point. The undersize continues with the water and goes to settling bins for subsequent treatment in Huntington mills. The overflow goes to a Frazer & Chalmers gravel-pan designed to catch any fine gold that may have passed the riffles in the sluice. The oversize from the flume grizzlies falls into bins, and is trammed to the mill breaker, a Dodge, thence to the battery bins. The stamp mill consists of 10 batteries of five stamps each. The pulp passes over silver-plated copper plates, thence to Wilfley tables; the Huntington mills are also equipped with plates and Wilfley tables.

#### GOLD DREDGING.

*Dredging Practice at Oroville, Butte County, Cal.*<sup>21</sup>—This practice is discussed in detail by G. P. Grimsley. Four types of dredges are in use in California: (1) Risdon, (2) Bucyrus, (3) Urie, and (4) Marion.

The Risdon Dredge consists of a strongly framed hull of Oregon pine, in which the machinery is housed; at the forward end is the ladder consisting of a heavy lattice girder on which runs the endless chain elevator carrying buckets of from 3 to 5 cu. ft. capacity; the buckets have renewable nickel-steel lips. The belt travels over a square-top tumbler, and is driven from a train of gears and one belt from a 50-H.P. induction motor taking a tri-phase current at 1,000 volts; 25 H.P. is consumed when dumping 12.5 buckets per minute, giving a capacity of 150 cu. yd. per hour. The material from the buckets goes to a delivery plate, thence to a revolving screen, 4 ft. in diameter, 24 ft. long, perforated with 0.75-in. holes. The oversize goes to a stacker (bucket elevator) at the stern of the boat, which, together with the screen, is driven by a 20 H.P. induction motor. The undersize from the screen goes to a distributing box and over 300 sq. ft. of tables

<sup>19</sup> *Engineering and Mining Journal*, Vol. LXXII., 1901, p. 108.

<sup>20</sup> *Ibid.*, p. 355.

<sup>21</sup> *Ibid.*, Vol. LXXI., 1901, p. 823, and Vol. LXXII., p. 40.

made of cast iron covered with cocoa matting and expanded metal riffles. Most of the gold is caught in the first 9 in. The overflow goes to a sluice-box containing angle-iron riffles. Water is supplied by two centrifugal pumps requiring 30 H.P., one delivering 2,000 gal. per minute through a perforated pipe into the screen, and the other supplying the various grizzlies and the distributing box.

The Bucyrus Dredge is of the continuous bucket type, equipped with buckets of 3, 5, and 7.5 cu. ft. capacity. There are two types, single and double lifts. In the former the gravel is elevated in one lift sufficiently high for subsequent operations, while in the latter, the fines from the revolving screen are re-elevated by a centrifugal pump to the gold-saving tables. A crew of two men per shift and 200 H.P. are required on a 5-cu. ft. bucket machine. A double lift dredge on a six months' run averaged 2,200 cu. yd. per 24 hours, including all shut downs.

The Urie Dredge is of the endless chain belt type, with buckets of from 3 to 4 cu. ft. capacity, fitted with an automatic feed device by which they may be entirely or only partially filled. A dredge of this type with a capacity of 1,500 cu. yd. per day is driven by six independent steam engines using steam from two 50-H.P. boilers.

The Marion Dredge is of the dipper or steam shovel type, with dippers of from 1.25 to 2.5 cu. yd. capacity. The 2.5-cu. yd. machine is run by a 100-H.P. motor; the screens and side conveyor require a 10-H.P. motor; the tailings stacker requires a 10-H.P. motor; and the pumps require a 30-H.P. motor, making a total of 150 H.P.

The costs of dredging gravels on the Feather river range from 4 to 12c. per cu. yd. Twenty-five companies operate 26 dredges, and eight more are ordered. Of those in operation at the end of the year, 14 are Risdon, three are Bucyrus, three are Marion, two are Urie, and three are steam shovels. The estimated cost of a 5-cu. ft. bucket dredge is about \$25,000, which will work about 10 acres of gravel 30 ft. deep per year. Prospecting of gravel beds in California is now done almost entirely by Keystone drills.

*The Nome District.*<sup>22</sup>—The non-success of dredging in the Nome district has been due partly to severe climatic conditions and partly to machines unsuited to the conditions. The ground adapted for dredging is in narrow water channels. A contributing cause of failure in beach dredging has been the heavy surf.

The Knott dredge, which has been successful on canal work, is to be tried. This type of dredge has the advantage of being able to swing the ladder through 180° without moving the hull; this adapts it for waterways no wider than the hull. The lower drum over which the buckets pass has no guide flanges, but is equipped with an automatic device, so that when an obstruction is encountered the drum rises, and after the obstruction is passed it adjusts itself automatically.

*New South Wales.*<sup>23</sup>—In this State the inclined tables receiving material passed through the trommel, are covered with cocoa-matting, upon the top of which wire netting or expanded metal netting,—the latter is made of wrought iron,—is placed, and forms riffles to catch the gold. To collect the concentrates the cocoa-matting from the first table is rinsed in a box of water every night, and

<sup>22</sup> *Engineering and Mining Journal*, Vol. LXXI., 1901, p. 735.

<sup>23</sup> *Canadian Mining Review*, Vol. XX., 1901, p. 176.

those from the other tables once a week. The washings, or concentrates, are then treated in a "streaming-down box" and the gold separated from the worthless material.

*The New Zealand Bucket Dredges.*—A. C. Perkins<sup>24</sup> describes the types now in use. They differ but little from the American or Australian prototype; the gold saving appliances also are similar. Under favorable conditions costs run as low as 1.6c. per cu. yd. When working in unfavorable ground engine diagrams taken showed a variation in load of from 45 to 70 H.P. in three revolutions.

*An Aid to Gold Dredging.*<sup>25</sup>—This consists of an addition to the standard dredge of a pneumatic tube which may be raised or lowered through a depth of 65 ft., the lower mouth of the tube is placed on bed rock and the water expelled by compressed air. The tube is large enough to carry a track-way on which runs a track for hoisting boulders and bed-rock cleaning. The lower end of the tube is enlarged to allow men to work, and the upper end has the customary air-lock entrance.

*Pelton Wheels.*<sup>26</sup>—Water-wheels of this type have been substituted for steam power on the Consolidated dredge operating at Waipori, New Zealand. They have proved a complete success.

*Method of Saving Fine Gold of Snake River, Idaho.*—Mr. Wm. H. Washburn<sup>27</sup> describes some of the methods out of which have been evolved the processes now most successfully used for saving the fine gold of the Snake river. For many years a modified form of the rocker was used, usually of sufficient size to have burlap and silver-plated copper plates, the latter being placed in the bottom. Later the so-called "beach machine" found much favor, as it did not require motion; it consists of a sheet-iron screen set at an angle of from 25° to 30°, having below at a reduced angle a silver-plated copper plate, which catches most of the gold; the material passing from it is conducted to a table or sluice to catch the rusty gold. Much of the mining on a small scale is now done by these or similar machines. Another device is to cover the bottom of a sluice 6 to 12 in. wide with Canton flannel over which is placed a stout wire screen with 0.25-in. holes; the sluice should be cleaned often enough to prevent loss of black sand which is accompanied with gold.

In September, 1899, with coal at \$7.50 a ton, a dredge was operated at 3c! per cu. yd., not including wear and tear.

After reviewing the results of the methods used at Snake river, Mr. Washburn concludes: "First, the sand should be screened to as near the size of the coarsest particles of gold possible; second, to save all the gold the black or other heavy sand should be saved with it; third, it is necessary to scour the gold in the concentrates by some form of grinding. With these principles carefully and intelligently carried out there seems no reason why the percentage of gold saved should not be as high as 90%, or even 95%."

## A REVIEW OF PROGRESS IN THE CYANIDE PROCESS DURING THE YEAR 1901.

BY J. S. C. WELLS.

THE cyanide process has made very decided progress during the past year, especially in the United States and in Canada. A large number of plants have been erected, some being of considerable size, notably the new Homestake plant, with a capacity of 1,200 tons per day and the Smuggler-Union plant of 600 tons daily.

The slimes problem seems to have been very successfully solved in several works, the process used in almost all cases being some modification of agitating and settling.

A good example of dry crushing and slimes treatment is that of the Cochiti Gold Mining Co., of Bland, N. M., a description of which was given in the *Engineering and Mining Journal*, January 19, 1901. A few mills using wet crushing with cyanide solution in the mortars are in operation and the results are said to be satisfactory.

No improvements in the precipitation of gold and silver from cyanide solutions have been developed and in this country the process of precipitation with zinc shavings appears to be the favorite, although zinc dust is being used successfully by several large mills. The Waldstein or De La Mar patent covering the use of the latter substance has been declared invalid by the United States District Court of Idaho, and it is probable that the use of this method will increase, for it has some decided advantages over zinc shavings, yielding a much finer bullion and at no greater cost; furthermore the precipitation seems to be rapid and complete. The chief difficulty is in making it a part of a continuous process. The following mills treating in all over 3,000 tons per day are using zinc dust for the precipitation of the gold: Homestake Mining Co., South Dakota; Montana Mining Co., Montana; Republic Mining Co., Washington; De Lamar Mining Co., Idaho and Nevada; Chainman Mining & Electric Co., Nevada, and the Consolidated Mercur Co., Utah. The price of zinc dust is \$6 to \$7 per cwt., and the amount used is from 6 to 9 oz. per ton of solution.

The progress of cyaniding is summarized by States as follows:—

**California.**—The California King Mines Co. has recently contracted for a 1,000-ton mill at Picacho, 20 miles north of Yuma, Ariz. The ore will be crushed by rolls to 20-mesh size and treated in 10 cyanide tanks 40 ft. diameter and 5 ft. deep. After leaching, the tailings will be sluiced through bottom gates. The Golden Cross mines have a 140-stamp mill and large cyanide plant at Hedges, 25 miles northwest of Yuma. The Standard Consolidated Mining Co., at Bodie, treats ores containing so much clayey matter that about 45% run off as slimes. The process now in use is as follows: There are two tiers of vats and the tailings from the mill are run directly into the upper ones, from which the slimes overflow and run into settling ponds. During the year ending February 1, 1901, 10,067 tons (dry weight) of sands were treated, the extraction being 89.8% gold, and 41.8% silver. The consumption of cyanide was 1.65 lb., zinc 0.79 lb., lime 8.7 lb., per ton. The slimes of which, 5,878 tons (dry weight), were treated, are after settling and drying, mixed with a certain percentage of leached

sands and treated in the usual way. The extraction is 80·3% gold, 75·9% silver. Cyanide used 0·9 lb., zinc 0·64 lb., lime 7·78 lb.

The following mines are reported as having erected cyanide plants during the year:—

Calaveras County.—Keystone, 20 tons, and Calaveras group, the capacity of the latter is said to be large.

Eldorado County.—The Vandalia mine, 400 tons.

Kern County.—At the Exposed Treasure and St. John's mines, small plants.

Mariposa County.—The Hite mine, 100 tons.

San Diego County.—The American Girl mine, near Ogilby, 200 tons. The ore is crushed by Cornish rolls.

Trinity County.—Headlight, 200 tons, and Golden Jubilee, 20 tons.

Tuolumne County.—At the Eagle-Shawmut and Densmore, new plants.

Shasta County.—Mount Shasta Co., 50 tons.

Siskiyou County.—Golden Jubilee, 50 tons.

An example of what may be done by coarse crushing is given in the Cummings mine, near Callahan's, Siskiyou County. The gold in the ore is in an extremely fine state of division and by amalgamation yields only from 13 to 17%. The dry crushing plant which was installed was discarded after several months' trial, owing to the large amount of fines produced making the pulp so slimy that it could not be leached. It was then decided to try leaching the ore after it had been crushed to pass a grizzly set with bars 1 in. apart; the greater part of the material however was 0·25 in. or finer. The consumption of cyanide was 0·5 lb. per ton of ore and the time of treatment was from 72 to 90 hours, giving an extraction of 80%. The ore is oxidized iron pyrites.

Colorado.—The Smuggler-Union Mining Co. has a mill under construction which will treat 600 tons of tailings per day. The process will be similar to that used at the Liberty Bell, having the collecting vat placed above the leaching vat, using zinc precipitation, etc.

The new Dorcas pneumatic cyanide mill at Florence has a capacity of 120 tons per day. The ore averaging \$20 in value passes through crushers and coarse rolls to the sampling room, thence through a revolving dryer and through two sets of finishing rolls which crush it to 24-mesh size. The finely crushed ore is then roasted in a Holthoff-Wethey furnace, the product passing to the leaching tanks. Six tanks 30 ft. in diameter, 4·5 ft. deep, are fitted with air pipes in the bottom for the introduction of air during the leaching. The air is supplied at a pressure not exceeding 5 lb., about 1 cu. ft. of air per minute to each ton of ore being sufficient for agitation and oxygenation. The treatment generally lasts five days and leaves a value of about \$1 per ton in the ore. The residue is then sluiced out and concentrated on Wilfley tables. The tailings after this treatment average about 40c. per ton. The tanks are filled by a conveyor, and as soon as the bottom of the tank is covered with pulp a solution containing 10 lb. KCN per ton is run in gradually, the pulp at the same time continuing to flow in until the tank is full. The air is then turned on gradually and is kept on until the pulp shows an extraction of at least 90%. This generally requires about 30 hours. Whenever the air comes up unevenly through the

charge the ore has to be stirred by men with iron rods. The air is then shut off and the pulp allowed to settle for one hour. Percolation is then begun and the strong solution run off as quickly as possible, followed by a weaker one of 5 lb. KCN per ton. The operation is continued until the tests of the solution show only traces of gold. Water is then added to displace the KCN solution. The loss in cyanide is stated to be less than 1 lb. per ton. The dust resulting from the dry crushing is collected and treated with cyanide, without previous roasting. From dust assaying \$51.20 per ton the tailings contained 80c. per ton. It is added to the roasted ore in the leaching tanks, 3 tons to each tank spread evenly on top of the charge.

The Peck cyanide mill treated Smuggler-Union and Marshall Basin tailings, and during the year its capacity was increased from 100 tons to 200 tons per day.

A number of small plants have been erected and operated during the past year in various sections of the State.

*Dakota.*—(By Charles H. Fulton.)—The condition of the industry is very prosperous, and the process is the dominant factor in the development of the Black Hills. The ores treated, with the exception of the Homestake tailings, are mainly of the siliceous Potsdam variety. This is quartzite carrying from 2 to 6% pyrites in the unoxidized ores. Considerable of the ore is oxidized and is the simplest to treat. But a very small percentage of the values in these ores are free milling. The unoxidized or pyritic ores, are known locally as "blue ores" from the bluish cast of the quartzite. In the Ragged Top district (Preston) where the Spearfish Gold Mining Co.'s plant and the Deadwood Standard Co.'s plants are located, the ores occur in the Carboniferous, and are mainly a siliceous limestone. The gold seemingly occurs on the cleavage planes of the rock in very fine films, allowing of very coarse crushing. The Potsdam ores, while all of the same general nature and appearance, are still widely different as regards the occurrence of the gold in them. Some have the gold on the cleavage planes, as in the limestone, as at the Wasp No. 2 cyanide plant on Yellow Creek, while others, as from Portland and Bald Mountain, have the values very finely disseminated, requiring very fine crushing. This explains the wide difference in the design of plants in the district. A few of the quartzite ores at Yellow Creek carry some antimony in the form of stibnite, however, not sufficient to cause difficulty in cyaniding. F. C. Smith considers tellurium as being often present in the Potsdam ores; if this be so, no attention has yet been paid to it in cyaniding. So far, all the ores cyanided are treated raw, although one of the new mills is installing a roasting furnace to treat the more refractory "blue ores."

Two methods of cyaniding, exclusive of the Homestake type, are in vogue: (1) Dry crushing by rolls, cyaniding the resulting pulp; and (2) Wet, fine crushing by stamps with cyanide solutions, separating the crushed product into sands and slimes by means of settling boxes, leaching the sands in the usual way, and treating the slimes by agitation and decantation.

Agitation is obtained by pumping from one tank to another by means of a sand or centrifugal pump, similar to the New Zealand practice. The crushing

by rolls in the dry mills varies much in fineness, some of the mills crushing to pass a 6-mesh screen, while others crush to pass a 16 to 20-mesh screen. This is necessitated by the dissemination of the gold. There are two mills using the wet crushing method, one the plant of the Dakota Mining & Milling Co., at Deadwood, and the other the Portland mill at Gayville, 2 miles from Deadwood. The rest of the mills in operation, as well as those in the course of construction, with the exception of the Homestake tailings plants, are dry crushing.

The Homestake Co.'s 1,200-ton tailing plant at Lead takes the tailings pulp from the Golden Star, Eighty, and Highland stamp mills. The pulp is conveyed to the cyanide plant in a 10-in. cast-iron pipe. On its way it passes through the classifier house, where some of the slimes are separated by means of eight large sheet iron cone-shaped classifiers. These cones have no upward or rising current, but as the ore pulp is charged by pipe at the center, the sands settle to the bottom and are discharged, while the slimes overflow at the periphery. The sands are then carried to the cyanide plant, where they are fed to seven additional cones and treated as above described. The slimes overflowing at the periphery are again discarded, while the sands are discharged to 4-compartment jigs of the Harz pattern, which act as classifiers. One cone feeds four jigs. The jigging is done on beds of pyrites concentrates, relatively coarse screens being employed, except in the last compartment. The stroke varies in the different compartments from 0.125 in. to about 0.5 in. The last compartment is widened out in order to accommodate the increased amount of discharge water, the overflow from which carrying the slimes is discarded. The continuous hutch discharge is taken by open launder to the revolving pipe distributors, which fill the leaching tanks, the peripheral overflow of the tanks still carrying off slimes. Lime in the form of an emulsion is added to the pulp launder which takes the jig discharge. There are 14 leaching tanks, 45 ft. in diameter, 9 ft. deep, of California red-wood, placed seven in a row, with one revolving distributor of the Butters type for each row, being moved from tank to tank by overhead track, as required. To get an even overflow at the periphery of the tank, the top of the staves are grooved to a depth of 0.5 in., and a soft pine tongue is inserted projecting from 0.5 to 0.75 in. above the top of the staves and a perfect level can be maintained by planing. It is the object to charge as much slime with the sands as possible and still leach in a reasonable time. For this purpose the adjustments are made on the jigs and distributors. The value of the pulp as it leaves the stamp mills is from \$1.25 to \$1.50 per ton. The amount crushed in the mills approximates 2,000 tons per day, while the cyanide mill treats about 1,200 to 1,300 tons per day. The difference, or 700 tons, is discarded as slimes which, while carrying considerable value, cannot be treated in the condition they are in. The proportion of slimes separated is about 35%. The sands are leached directly in the filling vats. Precipitation is carried on by zinc dust in five tanks 25 ft. in diameter, and 20 ft. deep, of California red-wood. The bottoms are inclined to one side, where a small sump is provided in order to drain the tank perfectly. The solutions drain from the leaching vats directly into the precipitating vats. The precipitation vats

are pumped out by duplex Prescott pumps, the solution going to filter presses made in the Homestake shops. The pulp treated by the mill is of a highly siliceous nature, often however, carrying some hornblende, the sulphides being mainly pyrite and pyrrhotite. The extraction is about 90% at a cost of 45 to 50c. per ton of material treated, probably nearer the latter figure.

The Dakota Mining & Milling Co.'s recently constructed wet crushing plant at Deadwood is of 60 tons' capacity. The ore from the Portland and Bald Mountain mines is the usual quartzite, with values very finely disseminated, which is crushed rough in a No. 2 Gates gyratory crusher, and passes to the storage bin, being fed therefrom by suspended chaffee feeds to two 10-stamp batteries of 900-lb. stamps, which crush through 20-mesh woven wire screens. The mortars are double discharge, but as the ore is crushed with 0.1% cyanide solution, some of the rear discharges are closed in order to keep the amount of solution from becoming too large. With both discharges open too much solution is used. The pulp discharge is caught by a launder in front of battery, conveyed to a sump from which it is elevated by a Frenier sand pump (capacity 6,000 gal. per hour) to a distributing box with launders to convey it to the separator boxes, one of which is placed above each sand tank. These separator boxes are 5×4 ft. in cross section, and 5 ft. deep, built in two compartments, each having in the bottom a circular discharge gate, hinged and closing tight against a rubber gasket by means of a long lever. The pulp flows into one compartment, the sand settling to the bottom, while the slimes overflow at one side. When one compartment is filled with sands, the pulp is deflected to the second compartment and the first discharged into the leaching vat below. The slimes flow by launder to the first slimes settling vat where they are allowed to settle. Four pounds of lime per ton of ore are added at the batteries to aid the slimes in settling; the acidity of the ore is very slight.

The sand vats are of red cedar, 20 ft. in diameter and 5 ft. deep, arranged in four sets of two each, one below the other for double treatment of the sands. It takes 24 hours to charge a tank by means of the separator boxes. The sands are leached with a 0.2% cyanide solution, followed by 0.1% solution and wash water. They are then shoveled through the bottom discharge gates, to the second vat below and re-treated. The time of transference is 12 hours, and the cost 5c. per ton. The total time of treatment is five days, including charging, transference and discharging, this last named being done by sluicing. The extraction made on sands is 83 to 84%, of which 8% is extracted in the second treatment.

There are six slimes vats of red cedar 20 ft. in diameter and 12 ft. deep, and after settling out the slimes from the solution in the first slimes vat the solution is drawn off as close as possible by siphoning, and is passed through the zinc boxes, thence to the barren solution sump tank. Fresh weak solution is added to the settled slimes, and the slimes mixture is then pumped by a sand pump to a second slimes vat, where the operation is repeated as above. The slimes are re-pumped four times, the last time wash water being added instead of weak solution; they are discharged by sluicing after the last settling. An extraction of 88% is made on the slimes, although only about 80% is saved,

the balance going out with the slimes, which retain about 100% of moisture. Only one wash water is used, as otherwise too great a bulk of solution is accumulated. The total time consumed in treating a vat of slimes is six days. Four 10-compartment zinc boxes are used to precipitate the solution.

The cyanide plant of the Wasp No. 2 Mining Co., on Yellow Creek, near Kirk, is a dry, coarse crushing plant of 90 tons' capacity per day. The ore is quartzite, the gold being on the cleavage planes, and in the seams and cracks so that coarse crushing only is necessary to make it available for solution. The value varies from \$3 to \$12 per ton, the main bulk averaging about \$4. It is mined very cheaply (85 to 90c.) by open-cut mining. The mill is built in terraces on a very steep hillside, and the ore is moved through almost entirely by gravity. It is hauled from the mine 750 ft. distant in trains of four cars, and charged into the main bin from which it passes to a No. 2 D. Gates crusher over a 4×8-ft. grizzly having 1·5-in. spaces between bars. The undersize and the crushed ore from the Gates go to the storage bin, from which it is fed by Tulloch feeders into one set of coarse Gates rolls 14×24 in., 80 revolutions per minute. The rolls discharge to a stationary inclined 2-mesh screen 7×1 ft., the oversize from which passes through the finishing rolls 14×24 in., operated at 100 r.p.m., and meets the undersize, the combined product being elevated by a bucket elevator to the shaking finishing screen, situated on a level with the coarse rolls. This screen is an inclined shaking 2·5-mesh screen, 16×2 ft., the lower half being stationary. Nearly all of the finished product passes a 6-mesh screen, the oversize from which being returned by gravity to the finishing rolls. The ore is charged from the finished product bin into the four leaching tanks of Oregon fir; each tank is 16 ft. diameter, 7 ft. deep and of 55 tons' capacity. For this purpose a 16-in. belt conveyor is used at a speed of 600 ft. per minute. A large 100-ton tank has recently been added, which gives the mill the capacity mentioned above. Tanks are charged in from 2 to 2·5 hours, the cyanide solution being added after the tank is about one-half filled. The strength of the strong solution is 6 lb. cyanide per ton of solution. About 15 tons of strong solution are run on and usually allowed to stand 3 to 4 hours, then it is drained, a weak solution being added at top to replace it. After this complete replacement it is allowed to stand a short time and then circulated for the balance of the leaching. The weak solution contains from 2·5 to 3 lb. cyanide per ton. About 50 tons of weak solution are used, followed by from 6 to 9 tons of wash water. To neutralize the acidity of the ore and give a protective alkalinity, 6 lb. of lime per ton are added before the ore is dumped into the first bins. The cost of cyaniding is from 85 to 90c. per ton. The precipitation is accomplished by zinc threads in specially constructed barrels, and very good results are obtained, the tailings solution having a value of from 4 to 10c. per ton. The extraction made is from 80 to 90% of the values, and the consumption of the cyanide amounts to about 0·5 lb. per ton of ore. The precipitates are treated by the usual sulphuric acid method. Zinc dust precipitation in the tanks, pumping the resultant mixture through filter presses, was tried at the mill, but discarded on account of the difficulty in the clean-up.

The new dry crushing cyanide mill of the Imperial Gold Mining & Milling Co., in course of erection at Deadwood, has facilities for roasting the heavier ore. The mill is modeled after the Florence pattern, and is built on the level, with the crushing, roasting and leaching departments inclosed in separate adjoining buildings. The entire product is handled automatically by belt conveyors and elevators. The crushing is done by a Blake crusher and Davies rolls, and the screening mostly by rotary screens. The sulphide ores are to be roasted in a Holthoff-Wetthey double-hearth furnace, the lower hearth being used for cooling. Ample provision is made for dust collection. The mill has an automatic Vezin sampler, which samples all material passing through the mill. The four leaching tanks are of 0.1875-in. steel, 35 ft. diameter and 6 ft. deep, and the other tanks also are of steel, including the zinc boxes. The following costs of milling are approximately correct, and but little variation from these figures will be found in modern practice. The cost of the wet crushing process per ton is \$2, or a little less. The cost of coarse crushing on lime ores by the Spearfish Co. before its plant was destroyed was from 75 to 80c. per ton. The cost of fine dry crushing and cyaniding has not yet been demonstrated. The old Golden Gate mill was too small and of too old a type to show modern practice, but as demonstrated there it amounted to from \$4.50 to \$5 per ton when treating a very limited amount. The actual cost, under modern conditions, is undoubtedly about \$2 per ton.

The following list comprises cyanide mills both operative and inoperative, together with those in course of erection January 1, 1902:—

Mills in operation.—1. Homestake, at Lead, S. Dak., 1,200 tons, stamp mill tailings.

2. Portland, at Gayville, S. Dak., 60 tons.

3. Wasp No. 2 Mining Co., near Kirk, S. Dak., 90 tons.

4. Cleopatra Mining & Milling Co., on Squaw Creek, 100 tons.

5. Dakota Mining & Milling Co., in Deadwood, 60 tons.

Mills not in operation.—1. Golden Gate, closed since September, 1901.

2. Shawmut Gold Mining & Milling Co., Black-tail Gulch, near Central City, 100 tons.

3. Annie Creek cyanide mill, Annie Creek, 100 tons.

4. Clevenger plant, Rapid City, 30 tons, chlorination tailings.

Mills in the course of erection.—1. Imperial Gold Mining & Milling Co., Deadwood, 100 tons.

2. Golden Reward Mining Co., Deadwood, 200 tons.

3. Spearfish Gold Mining & Milling Co., Preston, 250 tons; this mill takes the place of the one recently destroyed by fire, which was on the active list before its destruction.

4. Deadwood Standard Mining Co., Preston, 200 tons.

5. Homestake Central cyanide mill, at Gayville, 600 tons, tailings.

6. Little Blue Mining Co., Alder Creek, near Kirk, 50 tons.

There are several mills projected which will probably be built in the spring. The mills named under the heading "In course of erection," will be completed in two to five months from date unless delayed. Under the head of "Mills not

in operation," the Golden Gate mill will be probably permanently closed, unless it is more modernized. The Shawmut may in the near future increase its capacity. There are rumors of the Annie Creek mill restarting in the near future. The Clevenger plant, at Rapid City, has exhausted the supply of tailings from the chlorination mill, and is being dismantled.

Aside from the larger plants above stated, there have been four plants along Whitewood Creek operating on Homestake tailings this summer. At the old Dakota plant (10 tons), Central City, an experimental plant, has been at work at intervals. The small mill at Gayville, known as the Parker, Gibbs & Cook mill, has been at work part of the time. The Deadbroke Mining Co.'s combined stamp and cyanide mill in Blacktail Gulch, has also been experimenting. There is a plant at Mystic, employing a secret cyanide process which has not as yet treated ore on a commercial scale. Aside from the above mentioned plants, there are two or three smaller ones not operative at the end of the year.

*Idaho.*—In this State cyaniding seems to have made but little progress, for, with the exception of the mill of the De La Mar Mining Co., there are only a few small plants in operation.

*Montana.*—Many new plants have been erected during the year, some being of considerable size, notably that of the Empire Co., near Marysville, with a daily capacity of 500 tons, the Montana Mining Co.'s plant in Deer Lodge County having a capacity of 400 tons per day, and several others, varying from 100 to 200 tons daily. The industry is confined principally to the following counties: Fergus, Deer Lodge, Lewis and Clarke, and Madison.

The Fergus County ores are well adapted to cyaniding and when crushed so as to pass a 0.25-in. round hole are said to yield a 90% extraction. A large proportion of the ore assays only about \$3 per ton. In many of the mills the method followed is crushing by stamps, amalgamating, and cyaniding the tailings. In others the ore is crushed in rolls and then treated directly in the leaching tanks. In some cases the tailings are so slimy that they cannot be treated by percolation, therefore agitation and decantation have been employed with good results.

*Nevada.*—A few new mills have been built in this State during the year, the largest being that of the Chainman Co., at Ely, with an estimated capacity of 300 tons per day. This plant was described in the *Engineering and Mining Journal*, December 7, 1901. The Ely Mining & Milling Co. also has a new 50-ton plant which went into operation last spring.

At Tuscarora the Dexter Gold Mining Co. treated 100 tons per day, and near the same place the Bull Run Mining Co. has put in a new plant. The Cuyahoga Co., of Lyon County, also has completed a new mill. The process in use differs at the various mills.

At the Dexter plant, treating slimy ores, the method, as described by William Magenau, is quite different from that at the Chainman. The ore is crushed with stamps and amalgamated, the tailings going to settling tanks equipped with Butters and Mein distributors. The settlers catch 51% of the material run into them, the overflow carrying the slimes being run into ponds and settled. As soon as one pond is full the stream is turned into another and the former

allowed to dry for several months. The climate is so dry that in this time the upper few feet of the material become well baked. It is then put into cars by means of wheeled scrapers and carried to the leaching tanks to be mixed with the sands. As soon as a settler is full of sands they are shoveled into cars through a hole in the bottom and carried to the leaching tanks, where they are mixed with the dried slimes in the proportion of one car of sands to one of slimes. The mixture is leached continuously for from three to five days with a 0.2% solution of cyanide, the solution running in at the top as fast as it runs out at the bottom. Before discharging, a single water wash is given after the charge has been allowed to drain for several hours, or until no more solution runs off. The cyanide solutions go directly to the zinc boxes. The sands average \$1.57 gold and \$1.70 silver and the slimes \$3.19 gold and \$5.03 silver. The extraction is 66.8% of the gold and 37.7% of the silver. At the Ely mine a dry crushing process is used; the ore after passing through a crusher is dried in a rotary furnace and then crushed to 20-mesh size in rolls, from which it goes to the leaching tanks. The ore leaches easily and the extraction is 80%.

*New Mexico.*—The Cochiti Gold Mining Co., of Bland, has in successful operation a method of treating the dust from their dry crushing mill, which has been described by Charles S. Hurter in the *Engineering and Mining Journal*, January 19, 1901. Here 98% of the dust will pass a 100-mesh screen. The process used is agitating and settling, the agitation being effected by steam and compressed air, the latter being under 60-lb. pressure. The steam is used to heat the charge, as it was found that the air on expanding cooled it too much. The mixture of air and steam is admitted through 1-in. horizontal iron pipes in the bottom of the tank. The pipes have 0.0625-in. holes in the under side for the escape of the air and steam. In 24 hours 94% of the total values are in solution, using a solution of cyanide of 3 lb. per ton, but only 80% is recovered, due to the solution going to waste in the slimes. To neutralize the acidity of the ore and to aid the settling of the slimes, lime is suspended in a wire basket in the upper part of the tank. The cost of treatment is given as \$1 per ton.

*Utah.*—In the Mercur district cyaniding has been active and a large quantity of ore has been treated. The tailings at Manning are being treated and satisfactory results are reported. The Annie Laurie Co., of Piute County, completed a large new plant this year that has been running successfully. In addition to the plants above mentioned a few small ones have been built.

*Washington.*—Cyaniding in this State has been confined principally to the mill of the Republic Power & Cyaniding Co. Although this mill was closed in July, 1901, a description of the plant and process will be interesting as these ores were for some time a puzzle to metallurgists. Mr. D. C. Jackling has kindly furnished the following details of the process:—

The new plant, started in October, 1900, had a rough-crushing capacity of 100 tons and a milling capacity of 200 tons in 24 hours. The ore was dry ground to 60-mesh, roasted "dead," cyanided by direct percolation, and precipitated with zinc dust. The ore is quartzose, dense, hard and tough, often with banded white to black layers, and the numerous fractures usually coated with a soft

white substance like amorphous silica. As it comes from the mine it contains  $\text{SiO}_2$ , about 90%;  $\text{CaCO}_3$ , up to 5%, averaging 1.5%; S, up to 1%, averaging 0.5%; Cu, up to 0.1%, averaging 0.01%; Pb, Zn, As, Sb, sometimes in traces and Te none. The proportion of silver to gold in the ores treated was about 3.2 oz. silver to 1 oz. gold. The average for the district is about 5 to 1. Previous to the present plant several thousand tons of ore carrying 3 to 4 oz. gold, were treated by the Pelatin-Clerici process. It was ground wet in ball mills to from 80- to 120-mesh but under the most favorable conditions less than 90% of the gold dissolved. On 1.5 oz.-ore, the extraction decreased to 70%. These ores show scarcely any free gold even under the microscope and it is hard to account for unless, as suggested by Chatard and Whitehead, the gold particles are enveloped in a film of hydrated iron and aluminum oxides.

Calcination of the ore removed many of the difficulties, the only objection being a lessened extraction of silver. Coarser crushing can then be used and the roasted product leached by percolation in deep tanks.

The ore is put through a No. 5 Gates crusher, then through a Gates fine crusher (style H.), then through 15×36-in. Gates rolls. The crushed ore is sized here to about 0.5-in. before drying. The sampled ore goes to the main storage bin above the fine crushing department from which it is fed automatically to the cylindrical dryers of which there are two, each 26 ft.×60 in. The fine crushing department contains besides the dryers two sets of 15×36-in. and two sets of 15×26-in. Gates rolls, six 30-in. Griffin mills, six 8-ft. Jeffrey Columbian separators, etc. The rolls are in two series of a 36-in. followed by a 26-in., each series being served by one dryer and serving in turn three Griffin mills. These mills have 40-mesh screens set at an angle of about 40° and deliver a product 96% of which will pass a 60-mesh screen. The drying, grinding, screening and accessory machinery in this department requires about 1.25 H.P. per ton finished ore. Using rolled steel shells of best quality on the rolls and rings and dies of the same material in the Griffin mills the steel consumed per ton ore is about 1.25 lb. Dust chambers connected by large exhausters with the chief sources of dust are provided.

The following table gives the average of samples taken daily of finished mill pulp:—

|                                        |       |                                        |        |
|----------------------------------------|-------|----------------------------------------|--------|
| Remaining on 40 mesh.....              | 1%    | Through 120 mesh—remaining on 150..... | 10.50% |
| Through 40 mesh—remaining on 50.....   | 1%    | Through 150 mesh—remaining on 200..... | 8%     |
| Through 50 mesh—remaining on 60.....   | 2.50% | Through 200.....                       | 5%     |
| Through 60 mesh—remaining on 80.....   | 7%    | Total.....                             | 100%   |
| Through 80 mesh—remaining on 100.....  | 3%    |                                        |        |
| Through 100 mesh—remaining on 120..... | 10%   |                                        |        |

The finished pulp passes to the roasting furnaces, of which there are three of the straight line type with hearths 100×12 ft. The tops of these furnaces are covered with heavy corrugated iron and are used as a cooling floor for the roasted ore, along which it is moved by the returning rabblers, and during the last 25 ft. is sprayed with water. To yield good results the ore requires a surprisingly high temperature and long exposure to the heat and an almost complete expulsion of the sulphur.

The leaching plant contains 16 steel leaching tanks 22 ft. square by 6.5 ft.

deep, each of 110 tons' capacity. Three steel solution and standardizing tanks 14 ft. diameter by 10 ft. deep are also located in this section on a platform 12 ft. above the tops of the leaching tanks.

In the precipitating department are two precipitating tanks 10 ft. diameter by 8 ft. deep, two gold-solution tanks 14 ft. diameter by 10 ft. deep, one sump tank 24 ft. diameter by 5 ft. deep, all tanks being of steel. Solutions are handled by two Root rotary pumps. The slimes from the zinc dust precipitation are collected in four 24×36-in. Johnson filter presses. Vacuum is supplied for the leaching tanks by an 8×10-in. triplex power pump. The first solution 0.5% KCy is run in from the bottom of the charge until the whole is thoroughly saturated, percolation is then started and proceeds by gravity alone for 72 hours, after which vacuum is used. About 20 tons of this solution, besides that necessary to saturate the charge, are run in requiring from 36 to 48 hours. Weak solution, 0.3 KCy, is then run in until tests show the extraction to be nearly finished. About 40 or 50 tons of this are used during a period of from 72 to 84 hours. Wash water to the amount of 20 or 25 tons is now used and requires from 48 to 60 hours to drain. The total time required for loading, leaching and discharging a tank is almost nine days, and the total solution and wash water used, exclusive of that used to saturate the charge, is about 85% of the weight of the ore. The tanks are discharged through openings in the bottom. Filling and unloading costs about 11c. per ton. All solutions from the leaching tanks, including wash water, run into the same gold-solution tank and after precipitation the mixed solution becomes the weak one for succeeding tanks, strong solution being made up from it by addition of cyanide in lumps. Sufficient caustic soda is used to keep the alkalinity of the solutions at about 0.3%. When no lime is present the amount used is about 0.8 lb. per ton ore. The consumption of cyanide averages 1.18 lb. per ton ore. On 0.75 oz.-ore, the gold extraction by bullion produced was, 91.3%, and silver 15.6%. Precipitation is effected by zinc dust, 20 tons of solution at a time having the necessary amount sifted in while the solution is being agitated by compressed air. The amount required is about 0.95 lb. per ton ore, or 1.25 lb. per oz. of gold. If the alkalinity of the solution is kept at the proper standard the precipitation is rapid and complete, except in the presence of appreciable amounts of copper, when it becomes difficult. The precipitates and slimes are collected in filter presses and refined in the usual way by treatment with sulphuric acid, etc. The resulting bullion is about 900 fine in gold and silver.

CYANIDE PATENT LITIGATION IN 1901.—A case of considerable interest regarding the use of zinc dust or fume as a precipitant of gold and silver from cyanide solutions was recently decided by the United States District Court for Idaho. The suit was brought by Capt. J. R. De La Mar against the De Lamar Mining Co. to prevent the latter using zinc dust as a precipitant, and claiming that such use was an infringement of United States Patent No. 607,719, of March 9, 1896, covering certain improvements in the cyanide process. The court decided against the plaintiff and held that the patent was anticipated by prior publications and patents. It is supposed that Captain De La Mar will carry the case up to a higher court for final decision.

The claims of this patent are as follows:—

"Claim 1. The process of extracting precious metals from cyanide solutions, which consists in treating said solutions with zinc dust, to wit, the herein described material composed of zinc and zinc oxide, in a state of agitation, substantially as described.

"Claim 2. In the process of extracting precious metals from cyanide solutions the use as a precipitating reagent of a definite quantity of zinc dust in a state of agitation, the quantity of said zinc dust being supplied in only a sufficient quantity to thoroughly precipitate the contained metals, substantially as described.

"Claim 3. The process for extracting and recovering precious metals from their ores and which consists essentially of the following steps: First, subjecting the ore in a powdered state to the action of an aqueous solution of a cyanide; second, supplying to the solution charged with the precious metals that quantity of zinc dust determined to be exactly sufficient to precipitate said metals; third, agitating said solution and said zinc dust until said metals are precipitated, and said zinc dust is absorbed; fourth, recovering the precious metals from the valuable precipitate of the preceding steps by filtration or other process, substantially as described."

With regard to the use of zinc dust prior to the application for the patent, H. L. Sulman,<sup>1</sup> after speaking of the different methods of precipitation in use and describing the requirements demanded of a metallic precipitant, goes on to say that all the conditions are fulfilled "by the product known as zinc fume. \* \* \* It is a commercial by-product \* \* \* being the condensed metallic vapor in a state of extreme division." "It is an impalpable metallic flour and is seen under the microscope to consist of spheres more or less coated with oxide." This oxide, he says, retards somewhat the precipitating action and he recommends treating the product with dilute ammonia or some similar solvent of zinc oxide, thus leaving the zinc clean. "A small portion of this preparation agitated with a very dilute solution of auro-potassic cyanide permeates the whole volume of liquor rendering it slightly and uniformly cloudy \* \* \* and almost immediately determines the precipitation of the gold." "I have treated considerable volumes of gold solutions of varying strengths of cyanide and with an expenditure of zinc fume never exceeding 0.5 lb. per ton of ore have obtained precipitates which seldom contained below 97 to 98% of the gold originally present in the liquor." "When the solutions are rich in metal (or over 0.3 oz. per ton) the addition of zinc fume of from three to four times the weight of gold present has been sufficient to completely precipitate the latter. Very dilute solutions strangely enough require rather more than this."

It will be seen from the quotations given that every claim of the Waldstein or the De La Mar patent is fully and clearly anticipated by the process described by Sulman. The only difference between the two is in Sulman's treatment of the zinc dust with an ammoniacal solution so as to remove the oxide as he says the presence of the latter (the oxide) renders the action of the untreated product somewhat slow as a gold precipitant. From this it is plainly evident that he knew

<sup>1</sup> *Institution of Mining and Metallurgy*, London, Feb. 20, 1896.

that zinc dust in its untreated state would precipitate gold, but not quite so rapidly as when freed from the adhering oxide.

His United States Patent No. 576,173, filed February 25, 1895, also clearly shows that he did not consider it possible to patent the use of zinc dust alone as a precipitant, for all he attempts to cover in his patent is the process for removing the zinc oxide so as to make the zinc more active, and a special form of apparatus in which to make the precipitation.

Aside from Sulman's work it does not seem possible that such a patent could be valid, for even Dr. Waldstein must admit that it is the zinc of the zinc dust that causes the precipitation and not the oxide. Such being the case, in what way does it differ from the ordinary zinc precipitation, except that the zinc is in a more finely divided state, a condition which was well known to be favorable to precipitation?

*Australia.*—According to Mr. A. G. Charleton<sup>2</sup> cyaniding at Kalgoorlie is being carried on very successfully in spite of the slimy nature of the ore, due to the presence of silicates of magnesium and aluminum, and hydrated oxides of iron which form over 40% of the lode stuff. The practice varies considerably at the different mills. At the Lake View South the ore is crushed and amalgamated as usual, then goes through grinding pans and from there to Frue vanners, which yield concentrates containing 2 to 3 oz. gold per ton. These concentrates are cyanided at a cost, said to be 8s. 9d. per ton. The Associated mill treats the oxidized ore by dry crushing and cyaniding. The ore is first passed through crushers, then into a sizing trommel which separates the fines from the coarse rock. The fines are raised by a bucket elevator into a bin and the coarse ore goes to Krupp ball mills, the product from which is then raised in an elevator and joins the fines. The ore in the bins is discharged through canvas spouts into steel trucks holding about 1 ton and having W-shaped bottoms, the sides forming flap doors. Four or five of these trucks placed end to end are set on a carriage running on rails alongside the vats and which is moved back and forth by means of an endless rope controlled by a lever shifting the driving belt from a fast to a loose pulley. The vats hold 160 tons each, and it is claimed that this arrangement fills them more evenly and no trimming is required. Two men fill a vat in from 8 to 10 hours. The charge is kept under cyanide treatment for 10 days. The residues are discharged through bottom doors into trucks below. The cost of cyaniding is 5s. 6d. per ton. The Brown Hill mill also uses dry crushing in Krupp mills but the sizing is done by air separators and the coarse classified products are cyanided separately, in steel vats, and the slimes are treated by agitation and filter pressing. At this mill bromo-cyanide is used instead of potassium cyanide alone. Experience has shown that in some of the mills the slimes are of too low value to pay for treatment, while at others they are of comparatively high grade. This has led to two different methods of treatment. At the Great Boulder the dry tailings from the settling ponds are carried to the cyanide plant and both sands and slimes, after being broken up in a disintegrator are run into a sump, then pumped into a vat with radial arms and agitated in these vats with cyanide. When the gold is dissolved

<sup>2</sup> *Engineering Magazine*, June, 1901.

the pulp is filter pressed and the solution passed through the zinc boxes. The cost of this treatment in 1899 was 11s. 6d. per ton. The tailings after treatment contain 39 grains gold per ton and the loss in cyanide was 2.2 lb. At the Boulder Main Reef and North Boulder the sands are separated in one pond and the slimes in another. The sands only are treated, as the slimes are said to be worthless. The Lake View treats battery tailings containing about 80% slimes by first passing through a spitzkasten, from which the sands are elevated by a tailings wheel to six collecting tanks fitted with Butters & Mein's distributors. The sands which settle to the bottom still contain 40 to 50% of 100-mesh slimes. These sands are trucked to leaching vats in another building and cyanided for 10 days. The slimes from the distributors together with those from the spitzkasten are settled in tanks and then forced by compressed air into filter presses through which the cyanide leaching solution is pumped, and the residues finally washed with water. The process takes about 4 hours. The Ivanhoe uses still another plan. The battery tailings are first lifted to spitzluten which separate the coarse sands. These go to grinding and amalgamating pans, after which they pass through spitzkasten, the overflowing pulp from which, together with that from the spitzluten, goes to the cyanide vats. The Ivanhoe plant consists of sixteen 80-ton vats placed in two series one above the other, the lower vats being 5 ft. below the upper ones. The upper vats are provided with Butters & Mein's distributors, and are used both for settling and leaching. The slimes which overflow go to the slimes plant. The sands after the vats are filled to the required depth are drained and then leached for four days in the upper series, then dropped through bottom discharge doors to the lower series and again leached for four days. This double treatment is said to shorten the time required for extraction by two days. The capacity of the sand plant is 120 to 140 tons per day, and the cost of treatment, including grinding and amalgamation is said to be 5s. 6d. per ton. The slimes from the upper series of vats are run into settlers and after settling are passed into agitators with cyanide solution and agitated for 8 hours. The pulp is then forced through Dehne filter presses and washed with spent liquors. The capacity of this slimes plant is 150 tons per day and the extraction is said to be 80 to 90%. The New Zealand Government has decided to keep in force the cyanide patents which they bought four years ago, until the royalties received shall equal the expenditure. So far the royalties received, £4,253, are equivalent to 42.5% of the cost.

F. B. Stevens<sup>3</sup> gives the following description of his experience in treating acid tailings at the Wemmer Gold Mining Co., of Johannesburg. The tailings contained large quantities of ferrous and ferric sulphates as well as free sulphuric acid. The treatment first used was to give a water wash, then add lime and wash with caustic soda, and follow with cyanide. A large discrepancy between the actual extraction and that shown by assay had always existed, and it was suggested that the loss took place during the washing and was caused by the cyanide left in the vat from the previous treatment. It was then decided to wash the ore in a separate vat. The process finally adopted was as follows: The ore was washed with water for 12 hours then transferred

<sup>3</sup> *New Zealand Mines Record*, Jan. 16, 1901.

to another vat and mixed with lime and given a wash with caustic soda. To prevent iron hydrate from getting into the zinc boxes it was found advisable to fill the vat to a depth of 3 in. with sand and then to spread over it a layer of lime. This was found to catch a very considerable amount of oxide of iron. So soon as the washes began to come off distinctly alkaline the cyanide treatment was begun. By the above plan it was found possible to work these tailings successfully although the loss in cyanide was always above the average.

*Mexico.*—Messrs. Tays and Scheirtz<sup>4</sup> described their method of treating clay slimes at the Guadalupe mine of the Anglo-Mexican Mining Co. About 80% of these slimes were pure clay finer than 400-mesh, the balance being sand slimes passing 200-mesh. The gold value was about \$13 per ton. The method adopted was to agitate for 5 hours with 0.15% KCy in the proportion of 2.6 tons solution to 1 ton moist slimes, adding lime during the last part of the agitation, then settle for 7 hours and decant. After the first decantation water or weak cyanide was added in amount equal to that just decanted and the mixture agitated for one hour, then settled for six hours. The solution from the settling tanks then passed to a settling box, a long trough much wider at the discharge end than at the inlet. The clear solution from this passed to the gold solution tanks and from them to the zinc boxes. The extraction of gold was about 78%. Loss in cyanide 7 lb. per ton.

*Cyaniding Cupriferous Ores.*—According to Louis Janin, Jr.,<sup>5</sup> the pyritic ores of the Lydenburg (Transvaal) district present some interesting difficulties. These ores contain quartz, iron oxides, dolomite and small quantities of manganese, copper, bismuth and silver. The bismuth causes no difficulty, and the manganese dissolves only when an insufficient amount of lime is used. Not over 10% of the silver is recovered. The average amount of copper is about 0.4% and occurs as oxide, carbonate, in iron pyrites, and occasionally as copper sulphides and metallic copper. The latter is almost all caught on the amalgamating plates, and of the rest only a small amount is dissolved in the potassium cyanide. Unsuccessful attempts were made to dissolve out the copper with acid. The only method which has given satisfactory results depends on the property of potassium cupro-cyanide<sup>6</sup> to dissolve a small quantity of copper in the form of subcyanide, which is then precipitated by the Siemens-Halske process. A solution obtained in the ordinary course of practice containing cupro-cyanide but no free cyanide is employed. It was found that the tanks should not exceed 3 ft. in depth, otherwise the free cyanide would be exhausted. About 5 lb. of lime per ton is added to the sands and 15 lb. to the slimes; an alkaline wash is then used followed by one with a solution of about 0.07% KCN. In passing through the ore the free cyanide dissolves some of the copper as cupro-cyanide (?) which then dissolves more of the copper as subcyanide. "These subcyanides are converted by free cyanide into the normal cupro-cyanides. After the loss has been determined the strength of the following solution is roughly estimated, this will be from 0.1 to 0.2% free cyanide. In order to avoid loss of cyanide as much as possible,

<sup>4</sup> Paper read before the Mexican Meeting of the American Institute of Mining Engineers, November, 1901.

<sup>5</sup> *Engineering and Mining Journal*, Aug. 17, 1901.

<sup>6</sup> More probably cuproso-cupric cyanide.—J. S. C. W.

drawing off the solution is suspended when its strength reaches the normal point—about 0.05%. This strength is naturally determined by practice.” After the gold is dissolved a dilute solution is employed as in the ordinary process to remove all the gold. A small quantity of copper was found not to interfere with the precipitation of gold on zinc shavings, but when the point reaches 0.01 to 0.02% it causes a great deal of trouble, enveloping the zinc and preventing precipitation. For several years a system of intermittent washing of the zinc boxes with an excess of cyanide was used, followed by maintaining the normal strength of the solution by the addition of cyanide in a thin stream at the head of the zinc boxes, and frequently changing the charge of the compartments. When the zinc-lead couple became known it was introduced, and the precipitation of the copper as well as the gold was increased by it. To assure regular precipitation the free cyanide in the solution must be maintained between 0.03 to 0.12%, depending on the amount of copper present. Precipitated gold has a tendency to dissolve in these solutions from cupriferous ores unless the boxes are regularly soaked with cyanide as before mentioned. For example, a solution containing only 4 dwt. gold and 0.05% free cyanide has left the boxes when a cyanide was not employed, carrying 30 dwt. gold. Weak solutions were found to precipitate more copper than strong ones. By using the Siemens-Halske process these difficulties are avoided—the cyanide is regenerated and the gold and copper are precipitated as a hard adherent coating. On the anodes a hard crust of iron cupro-cyanide (?) is formed that causes the current to flow unequally between the plates, causing a tendency to short circuit. This may be prevented to some extent by hanging the anodes in cloth sacks, using as weak a current as possible and moving the lead strips daily. It is also advisable that connection between the sheet iron anode and the copper conductor be made by fine iron wire that will burn out if the current becomes too strong and call attention to the formation of a short circuit.

*Cyanide Solutions containing Copper.*—W. H. Virgoe<sup>7</sup> gives his experience in the testing of cyanide solutions containing copper both when using potassium iodide as an indicator and when silver nitrate alone was used. His conclusion is that when copper salts are present the use of silver nitrate alone is inaccurate, such solutions apparently showing free cyanide when none is present. When using the iodide as an indicator the results appear to be reliable. As an example he says “a solution containing 0.3% Cu and titrating 0.52% with silver nitrate alone may titrate 0.13% potassium cyanide correctly if potassium iodide be used.” He finds that in titrating pure solutions of potassium cyanide the amount of the indicator used makes no difference, but in strongly alkaline solutions or in those containing copper it affects the results very materially. The use of two or three drops of a 2% solution of potassium iodide is recommended as giving correct results except in cases where much free alkali is present when the results are apt to be too high. Cyanide solutions containing 0.3% or over of copper yield very poor extraction and it becomes necessary to purify them. This he says can easily be done by the lead-zinc couple as practiced at the Creston-Colorado plant at Minas Prietas, Sonora, Mexico. The details are those given him by Mr. Higgins,

<sup>7</sup> Paper read before the Institute of Mining and Metallurgy, December, 1901.

the superintendent. The plant has a capacity of 250 tons daily. "The solution coming from the tanks titrates about 0.23% KCN and flows first through fourteen ordinary zinc launders  $18 \times 2.5 \times 2.5$  ft. in size—where the fine product is collected; secondly, from these launders the solution is taken through six other launders with zinc-lead in each compartment. I use 1.5 lb. lead acetate to 15 lb. zinc shavings; in other words, about 160 lb. of lead acetate for 7,500 tons ore." To form the lead-zinc couple the compartments in the zinc boxes used for this part of the process are filled with condensed water from the boiler and 1.5 lb. of lead acetate is dissolved in each. After solution, 15 lb. of zinc shavings are pressed into each compartment and allowed to stand for half an hour or more. The solution after passing through the plain zinc boxes where most of the gold and silver is precipitated, then flows through the lead-zinc boxes prepared in the way just described which remove a large proportion of the copper. Solutions that previously contained from 3 to 4 lb. copper per ton are by this treatment reduced to 1.25 lb. Cu, which amount causes no trouble. The product from these boxes containing about \$2 per lb. in gold and silver and 45% Cu is sent to the smelters. Mr. Virgoe suggests as another possible method of purifying the solution precipitating the copper with zinc dust and then removing the zinc by treatment with an alkaline sulphide. He gives the following method for the determination of gold and silver in cyanide solutions: To 1,000 c.c. of the solution, add an excess of copper sulphate and acidify with hydrochloric, nitric or sulphuric acid. The precipitate, which is white and flocculent contains all the gold and silver and the blue or green color of the filtrate indicates that an excess of the copper sulphate has been added. The precipitate is washed, dried and placed in a scorifier with lead. The results are accurate and the whole operation can be done in an hour and a half.

*The Bromo-Cyanide Process* has been adopted by several of the Australian mining companies, among them being the Lake View, the Hannan's Star and Brown Hill mills. The results are said to be very satisfactory. A test on 653 tons of sulphide ore at the Brown Hill mill yielding an extraction of 95.7% of the gold, and other results as high as 97.6% are said to have been obtained. The consumption of cyanogen bromide varied from 0.5 to 1 lb. per ton ore. These ores are sulpho-tellurides of very high grade, running from 1.51 to 3.5 oz. gold. The process is generally known there as the "Diehl." It is claimed that the combination of the two cyanides is capable of dissolving telluride of gold, whereas in simple cyanide it is insoluble. Also that no oxygen is necessary in the process and consequently it is especially well adapted to the treatment of sulphides such as concentrates, etc. That these claims are well founded seems to be established by the success obtained in Australia and with the mispickel ores of Deloro, Canada, which are well known to be very refractory. Mr. Wright in a paper read before the Canadian Mining Institute, 1901, gives the following particulars of the process as used there: The wet concentrates from the mill consist principally of mispickel, some iron pyrites with small amounts of copper and from 15 to 20% of quartz sands. These are dumped directly into the vats to a depth of 3 ft. (equivalent to about 40 tons) and a little lime added. After leveling, the charge is sampled by a 2-in. augur, 20 to 30 holes being bored to

the bottom of the charge. A short water wash is then given and as soon as the water has disappeared from the top of the ore the mixture of potassium cyanide and cyanogen bromide is run on to an amount approximately one-third the weight of the ore. The wash water still draining out is run through zinc boxes until on testing the solution with ferric chloride a distinct blue color is obtained. When this shows the solution is switched to the strong solution tank. Constant slow percolation has been found to yield the best results, so the solution after it runs through is brought up to strength and continued in circulation for 24 hours. By this time 60 to 70% of the gold has been extracted and it has been found advisable at this point to drain the charge and then turn it over by shoveling so as to break up and mix any lumps that may be present. The cyanide solution is again run on and the leaching continued until assays show the extraction to be complete. A weak cyanide wash is then given, followed by one of water only. The gold is precipitated by zinc fume, a Sulman's cone being used for the purpose. Ninety-nine per cent. of the gold in the solution is reported to have been obtained. The consumption per ton of concentrate is: potassium cyanide, 2 lb.; cyanogen bromide, 0.5 lb.; zinc fume 0.19 lb.; time of treatment, 80 to 100 hours; extraction of gold, 87 to 94%. The Gold Ore Treatment Co., which controls the patents for this process, gives the price of cyanogen bromide as 2s. 6d. to 3s. per pound, but expects shortly to be able to reduce the price. A factory is now being built in Australia to supply the demand in that country.

*Testing Cyanide Solutions containing Zinc.*—L. W. Green\* gives a method based on the following:—

- (1) Potassium ferrocyanide is neutral to phenol-phthalein.
- (2) One cubic centimeter of N/10 potassium ferrocyanide precipitates 0.75 c.c. N/10 zinc solution from dilute neutral solutions. (Sufficiently exact for technical purposes.)
- (3) When a dilute neutral zinc solution is precipitated by excess of sodium carbonate, the excess of alkali being afterward neutralized with N/10 acid using phenol-phthalein as indicator, a precipitate of basic carbonate of almost constant composition is obtained, *viz.*,  $3\text{Zn}(\text{OH})_2, 2\text{ZnCO}_3$ .
- (4) Zinc hydrate or carbonate treated with an excess of potassium ferrocyanide yields zinc ferrocyanide and potassium hydrate or carbonate as follows:—

The above reactions do not take place immediately and are only complete by neutralizing the alkali as formed.

(A) Total cyanide.—Add excess of sodium hydrate and a drop or two of potassium iodide and titrate with silver nitrate till a distinct permanent *yellow* cloudiness is formed. Result equals total cyanide which we will designate by T c.c.

(B) Hydrates of the alkalis and alkaline earths plus half the monocarbonate. (*Protective alkali.*)—Add excess of potassium ferrocyanide, then sufficient silver nitrate (as shown by A) to precipitate all of the cyanide present. A slight excess

\* Paper read before the Institute of Mining and Metallurgy, Oct. 17, 1901.

does not matter. The zinc is all precipitated as ferrocyanide and the alkali hydrates and carbonates are left in solution. Phenol-phthalein is then added and the solution titrated with N/10 nitric acid. Result equals the protective alkali (p).

(C) Estimation of the alkaline hydrate.—Add excess of barium chloride, sufficient to precipitate all the sulphates and carbonates, and then proceed as in the last test. Result equals the alkaline hydrates (h). In case no hydrates are found bicarbonates may exist in the solution. These can be determined by adding a known quantity of standard alkali and repeating the above test.

(D) Determination of total cyanides, ferrocyanides, sulphocyanides, chlorides, etc.—Add sufficient acid (as shown by B) to neutralize the alkali present, then a drop of potassium chromate and titrate with silver nitrate until a faint permanent red color appears.

(E) Ferrocyanides.—Add about 10 c.c. N/10 sodium carbonate, then sufficient silver nitrate to precipitate all the cyanide (T c.c.) and shake well. The ferrocyanide present will all be precipitated by the zinc in the solution, and any excess of zinc will be thrown down as basic carbonate, and there will be an excess of sodium carbonate. Add phenol-phthalein and neutralize slowly with N/10 nitric acid. Add about 1 c.c. more of the acid, shake, and add solution of sodium carbonate drop by drop till the clear solution is just faintly pink. Add excess of potassium ferrocyanide and the solution becomes strongly alkaline, due to the reaction between the basic zinc carbonate and the potassium ferrocyanide. Titrate with N/10 nitric acid. Result equals the zinc less what has been precipitated by the ferrocyanide originally present (S).

(F) Zinc.—Add sodium carbonate as in previous test then sufficient silver nitrate (as shown by D) to precipitate all cyanides, ferrocyanides, etc., and the whole of the zinc will be precipitated as basic carbonate and there will be an excess of sodium carbonate remaining in the solution. Add phenol-phthalein and neutralize as in last test. Add excess of potassium ferrocyanide and titrate with N/10 acid. Result equals the whole of the zinc, plus any copper or cadmium which may be present in small quantities, (Z). In all of the above tests 50 c.c. of the original cyanide solution is taken. If the standard solutions used are N/10 nitric acid, and a solution of silver nitrate containing 13.05 g. per liter then the following are the factors for the different results:—

|                                     |                            |
|-------------------------------------|----------------------------|
| Total cyanide (as KCy)              | $=T \times 0.02\%$ .       |
| Protective alkali (as KOH)          | $=p \times 0.0112\%$ .     |
| Alkaline hydrate (as KOH)           | $=h \times 0.0112\%$ .     |

| Zinc                                | $=Z \times 0.0081\%$ .     |

**Electromotive Force of Metals.**—The most important contribution to the theoretical side of the subject that has recently appeared is an article by Prof. S. B. Christy having the above title, which was published in Vol. XXX. (p. 864) of the *Transactions of the American Institute of Mining Engineers*.

In the following review considerable matter of interest has been omitted, attention being called only to those sections which bear most directly on the cyanide

process. In the original paper the results of his determinations of the E.M.F. of various metals and ores in solutions of potassium cyanide of different strengths are given. A portion of the table is as follows:—

|                       | Strength of KCN Solutions. |                           |                             |                                |                    | Strength of KCN Solutions. |                           |                             |                                |
|-----------------------|----------------------------|---------------------------|-----------------------------|--------------------------------|--------------------|----------------------------|---------------------------|-----------------------------|--------------------------------|

In above table M=one gram-molecule of KCN (65 g.) dissolved in 1, 10, 100 or 1,000 liters of water.

The meaning of the signs + and — may not be clear to those who have not kept in touch with the modern theories of electro-chemistry, and for their benefit some explanation is necessary. In order to understand just what they signify, a clear idea must be had of the nature of solutions.

The phenomenon of osmosis and the pressure produced by it have long been known, but it remained for Pfeffer to show how to measure this pressure, and for Van't Hoff to prove that it followed the laws of gases in every particular, and that in a solution "the osmotic pressure of a dissolved particle is exactly equal to the gas pressure of a gaseous particle at the same temperature and concentration." That is to say, for example, in a solution of sugar in water each molecule of sugar in the solution will exert exactly the same pressure as would each molecule of any gas, such as hydrogen, of equal molecular concentration and at the same temperature and volume, or, in other words, the molecules of sugar in the solution obey exactly the same laws as if they were gaseous particles.

It was soon found that there were exceptions to the rule, and that some substances gave abnormal osmotic pressure when in solution. Those acting in this manner comprised almost all the bases, acids and salts, and until Arrhenius cleared up the difficulty it was a great stumbling block for the new theory of solutions. He proved, however, very conclusively that these substances when in solution are dissociated, to a greater or less extent depending on the degree of dilution into so-called ions. The molecule of potassium chloride, for example, would dissociate with the ions K (potassium) and Cl (chlorine), the metallic ion (K) carrying a charge of positive electricity, and the other a negative charge. This dissociation does not seem so strange when we remember that some gases give abnormal vapor densities, and that it is now fully established that this deviation from the law is due to dissociation of the molecule.

One point that is of special interest in this connection is that only those substances conduct the electric current which are at least partially dissociated, and therefore the conductivity is due to the dissociated parts or ions. Every one is

familiar with the fact of vapor tension or pressure and knows that when a solution or solid evaporates into a closed space an equilibrium is established at a certain definite pressure for a certain temperature. Nernst reasoned as follows: "If, in accordance with Van't Hoff's theory, we assume that the molecules of a substance in solution exist also under a definite pressure, we must ascribe it to a dissolving substance in contact with a solvent, similarly a power of expansion, for here also the molecules are driven into a space in which they exist under a certain pressure. It is evident that every substance will pass into solution until the osmotic partial pressure of the molecules in the solution is equal to the solution tension of the substance." Applying this principle to metals, suppose a metal be placed in water—the metal, owing to its solution pressure ( $P$ ) tends to send ions into solution, these ions being charged with positive electricity, leave the metal negative and there is soon formed the so-called double layer of Helmholtz, that is, the positive ions in the solution and the negative metal attract each other and a certain potential difference is produced. Solution of the metal can only go on so long as the solution pressure ( $P$ ) is greater than the electrostatic attraction of the double layer. This is in pure water—with a metal in a solution of one of its salts another force comes into play, due to the metallic ions of the metal already present. The osmotic pressure ( $p$ ) of these ions opposes the entrance of new ions of the same kind. If the osmotic pressure is exactly equal to the solution pressure of the metal the latter will yield no ions. It will not become negatively charged and no double layer will form, consequently no potential will be produced. If the osmotic pressure is less than the solution pressure ions of the metal will not go into solution until  $P=p$ , and the metal will be negatively electrified and the solution positively, and an electric double layer will be formed and a potential difference established and the direction of the positive current will be from the metal to the solution. When the osmotic pressure is greater than the solution pressure the reverse action takes place and metallic ions from the solution carrying their positive charges are precipitated on the metal and the solution becomes negative and the metal positive, and the positive current travels from the solution to the metal. This action goes on as in former case until  $P=p$ .

We are now in a position to understand the meaning of the signs  $+$  and  $-$  in the table, the  $+$  corresponding to the second case  $P > p$ , that is, the metal tends to dissolve in the solution. The  $-$  sign corresponds to the last case  $P < p$ , that is, the metallic ions in the solution tend to precipitate on the metal, and unless outside energy is brought into play the metal will not dissolve.

To make the matter still clearer, take the common Daniel cell containing zinc in zinc sulphate and copper in copper sulphate. It has been found by experiment that zinc in zinc sulphate is  $+$  ( $P > p$ ) with a potential difference of  $+0.521V$ , and that copper in copper sulphate is  $-$  ( $P < p$ ) with a potential difference of  $-0.585V$ , hence in the combination of the two the zinc tends to go into solution with a force equal to  $0.521V$  and the copper ions in the solution tends to precipitate on the copper (and producing a current in the same direction as the zinc ions) with a force equal to  $0.585V$ , and as these two forces both act in the

same direction the total voltage of the cell will be equal to their sum, viz., 1.10V. It may be represented in this way:—

The arrows indicate the direction of the current.

If both metals had had  $P > p$  then the two forces would have been in opposite directions and the voltage of the cell would be the difference between the two. Take, for example, Zn in M/10KCN and gold in M/KCN, the result (see table of E.M.F.) would be expressed as follows:—

and the E.M.F. of the couple would be 0.54V.

Knowing now the meaning to be attached to the signs, as pointed out by Prof. Christy, many points of interest will be found in the table bearing on the solubility of the various substances in potassium cyanide. The action in copper minerals is worthy of note, apparently showing that bornite and copper glance are soluble in solutions of as high dilutions as M/10 (0.65%) and the latte even at M/100 (0.065%); bornite, however, in a solution of that strength being insoluble. Chalcopyrite and all the other sulphides given are seen to be strongly electro-negative (insoluble). Prof. Christy calls attention also to the fact "that a particle of gold in contact with a particle of pyrite forms a galvanic couple in M/1 or 6.5% KCN equal to +0.65V; in M/10 or 0.65% KCN solution +0.65V; and in M/100 or 0.065% KCN +0.57V." Between zinc and gold under the same circumstances in solutions of M/1, M/10 and M/100 there are voltages of +0.54V, +0.50V and +0.77V, the zinc going into solution and the gold being precipitated. According to these figures, zinc should readily precipitate gold from very dilute solutions, and its failure to do so in practice may be due to the formation of films of cyanide or zinc hydrate on the surface of the gold, thus preventing contact. The fact that the addition of a small amount of potassium cyanide in the zinc boxes starts precipitation again seems to favor this explanation. As to gold, it ceases to dissolve in potassium cyanide at some point between M/100 and M/200 and that at M/1000 it is quite strongly negative.

On plotting the results obtained with solutions of various strengths it was found that the voltage curve crossed the zero point at a dilution of 0.044% KCN, that is, gold ceases to have any tendency to dissolve in solutions weaker than this. But much weaker solutions have been used in practice, and Prof. Christy's experiments show that solutions as dilute as 0.00325% KCN or possibly even so dilute as 0.0016% have a solvent action on gold. This apparent contradiction he explains in a very satisfactory manner, as will be shown later in this article. In order to understand his explanation it is necessary to become familiar with his method of determining the E.M.F. of the different metals, etc. For this Ostwald's normal electrode was used, which consists of mercury covered with a layer of mercurous chloride and a normal solution of potassium chloride. This is contained in one vessel and the metal to be tested is placed in another con-

taining the KCN solution, the two vessels being connected by a siphon filled with a solution of potassium chloride. The E.M.F. of the normal electrode has been very exactly determined as  $-0.56\text{V}$ . That is, the mercury ions of the solution tend to precipitate themselves on the surface of the mercury with a force of  $0.56\text{V}$ . In other words, the positive current tends to flow through the solution to the mercury, the conditions in the complete cell being as follows:—

Suppose a solution is taken of KCN of  $0.065\%$  and in determining the voltage of the complete cell find it to be  $0.65\text{V}$ , it is plainly evident that the E.M.F. due to the gold is  $+0.09\text{V}$ , being the difference between the total voltage  $0.65$  and that of the normal electrode  $0.56\text{V}$ . It is also evident that the current at the gold electrode is in the direction of the arrow.

Suppose now a solution of KCN of  $0.0065\%$  is used in place of the stronger one and on determining the E.M.F. of the combination it is found to be  $+0.18\text{V}$ . It is plain that the gold no longer tends to go into solution ( $P < p$ ) and that the current due to it is reversed, thus:—

Here are two opposing forces, and since that of the mercury ions is the stronger, it determines the direction of the current in the cell, but owing to the counter action of the gold ions it has only a force of  $0.18\text{V}$ .

According to Prof. Christy, the action of a couple of this character will continue and the gold dissolve "so long as the E.M.F. of the combination is greater than zero and, as we have seen in my experiments, long after the electromotive force of the gold in the dilute cyanide solution has become zero. For the tendency of the mercury ions to discharge into the mercury electrode can only effect its purpose and cause a current by the simultaneous solution of the gold, that is, the tendency of the positively electrified ions of mercury to discharge themselves can cause the gold to dissolve long after its own electromotive force has ceased."

He then goes on to show that in the oxygen of the air we have a substance that acts practically in the same way as the mercury ions, producing a current that continues long after the E.M.F. of the gold has fallen below the zero point. This he proves by a very simple experiment made as follows: Two small porcelain cups were taken, one filled with KCN solution freed from oxygen and the other containing a similar solution saturated with oxygen. The two vessels were then connected by a siphon and a gold electrode placed in each and connected through a galvanometer and resistance coil. A current was found to flow through the solution from the electrode in the cup containing no oxygen to the one in the cup containing oxygen. In one experiment cited the electrode

in the cup free from oxygen lost 1.28 mg. and the other 1.73 mg. Many other experiments showed that the current flowed in the same direction and that there was a solution of the gold in the cup containing no oxygen. The fact that more gold was dissolved in the cup containing oxygen than in the other he explains as being due to local action between the gold and the hydroxide (OH) ions. The appearance of the electrodes is also said to corroborate this explanation, for the one in the cup free from oxygen was more evenly acted on than the other, the latter being "eaten into in a remarkable manner."

Using hydrogen dioxide instead of air in the cell his results were even more conclusive, the gold electrode in the cup containing no oxidizer dissolving more freely than in the one containing the dioxide. In one case the former lost 13.25 mg. and the latter 9.2 mg., and in still another the losses were 24.06 mg. and 13.25 mg., respectively. In both cases the electrode in the solution containing no oxidizer suffered the greater loss.

The peculiar fact discovered by McLaurin,<sup>9</sup> that the maximum solubility of gold in cyanide is in a solution containing between 5 and 10% KCN is explained as due to the fact that under this condition the sum of the two forces tending to dissolve the gold is greatest. The E.M.F. of the gold has reached nearly its highest point and the E.M.F. of the oxygen is greater than in more concentrated solutions, for McLaurin proved by his experiments that the more concentrated the cyanide the less the amount of oxygen dissolved.

Here are two forces bearing an inverse relation to each other that tend to dissolve the gold, and their maximum effect is at the dilution named, viz., 5 to 10% KCN.

From the results of his experiments Prof. Christy concludes that in the cyanide process as practiced the solution of the gold is probably due to local action between it and the hydroxyl (OH) ions (formed by the action of O and H<sub>2</sub>O) of the solution, and that for all practical purposes an aerated cyanide solution of less than 0.001% KCN is without action in gold. He also states "that the differences of E.M.F. of metals in dilute cyanide solutions do not give much support to the so-called 'selective affinity' of dilute cyanide solutions for gold, the only common metal that shows any indication of such favorable action being copper."

*Assay of Zinc Precipitates.*—Charles H. Fulton and Charles H. Crawford<sup>10</sup> first tried the scorification method and found it very unsatisfactory, the results obtained being low, evidently caused by excessive volatilization and loss in the slags. The crucible method was then used and found to give the highest average result (after correction for loss in slag) on gold but not on silver. The loss of precious metals in the slag was found to be very variable and while the method in many cases gives the highest results in others it gives low ones, although the conditions as to charge and heat are the same in all cases. The most satisfactory charge by this method was one recommended by Magenau, viz., 0.1 assay ton precipitates, 70 g. litharge, 5 g. sodium carbonate (dry), 1 g. flour, 5 g. silica and 2 g. borax glass. A combination method was then tried, the precipitate being

<sup>9</sup> *Journal of the Chemical Society*, London, LXXXIII., p. 781.

<sup>10</sup> *School of Mines Quarterly*, January, 1901.

first boiled with nitric acid and then salt solution added to precipitate the silver, as well as some lead acetate and sulphuric acid. The precipitate was filtered, washed and scorified. The results for gold were found to be far too low, while for silver they were higher than by the crucible assay. This seemed to indicate that some of the gold had dissolved in the nitric acid and tests made proved that such was the case. This method was replaced by one using sulphuric acid instead of nitric acid as follows: 1.1 assay ton of precipitate was heated with 20 c.c. concentrated sulphuric acid and 60 c.c. water. This was boiled for one hour, cooled, diluted to 100 c.c., and 75 c.c. salt solution, and 20 c.c. of lead acetate solution added, allowing the precipitate to settle for one hour, then, filtered, washed and dried. Care was taken to wash the precipitate into the point of the filter. The paper was burned off at a very low heat and the residue scorified until half covered over in the scorifier, then poured and the button cupelled. From 30 to 40 g. lead were used. The results were good and as uniform as can be expected with material of this kind. The gold is lower than in the crucible assay (about 6 oz. per ton) while the silver is higher. The slag corrections are relatively small. In conclusion the authors recommend either the combination sulphuric acid method or the crucible method, preferably the former. In using the sulphuric acid method care must be taken that the acid contain no nitric acid. The slag and cupels should be reassayed in order to add the proper corrections.

*Zinc versus Electrolytic Precipitation.*—(By Philip Argall.)—In THE MINERAL INDUSTRY, Vol. VI., I stated that "the method of precipitation by means of zinc has been very often criticised, but nevertheless it has stood the test of time, and for solutions running from 0.05% cyanide upwards, and low in gold, it is likely to continue for a considerable time to come the best precipitant of gold from cyanide solutions. To this strength at least electrical methods have a fair field; for solutions carrying over 0.10% cyanide I cannot see the slightest chance for electrical precipitation to compete with zinc."

A few months after writing the above, the results of large working tests with zinc alloys and couples clearly demonstrated that for any strength of solution, zinc can at least hold its own against electrical precipitation. Later when the process was in daily use, sundry improvements in details brought up the results considerably beyond my expectations. Complete records covering a period of 17 months, during which about 150,000 tons of solution were treated, showed that the average value of the solution entering the precipitators was 0.068 oz. gold, while that leaving was 0.005 oz. gold. The average strength of the solutions in cyanide being 0.031%, the precipitation of gold from these low-grade solutions is therefore 92.6%. A careful list of all the costs incidental to this precipitation for the entire period of 17 months showed that the actual expense of treating one ton of solution and marketing the bullion, was 1.5 cents. Reckoned on a basis of bullion recovered, the costs per oz. were: Zinc, etc., 12c.; crucibles, 4c.; acid, 1.106c.; soda, 0.4484c.; borax glass, 1.6036c.; niter and minor fluxes, 0.146c.; litharge, 0.306c.; coal and coke, 0.74c.; labor, 6.8c.; unclassified, 0.29c.; total, 23.84c.

The average assay of the wash water for December, 1900, showed 0.045 oz.

gold and 0.032% KCN before precipitation and 0.003 oz. gold and 0.028% KCN after precipitation.

Continuous samples of the solutions entering and leaving the precipitators were taken off and assayed every 12 hours, hence the foregoing averages for December, 1900, are based on two samples per day for 31 days, or 62 samples for each precipitator. The record for the 17 months previously described was taken in a similar manner, and all items of cost carefully tabulated; the results, therefore, are correct in all practical details for commercial work.

The precipitation averaged 94% and the gold value of solution leaving the precipitators was from 4 to 6c. per ton. There is nothing exceptional about these results, which represent what can be done with zinc under ordinary working, and indicate the conditions against which electrical precipitation must compete. The zinc consumption in the table is excessive, on account of close clean ups when active zinc was destroyed in order to recover values; this is a matter of importance in a custom mill, but of little consideration in a mine plant where the gold stock in the precipitators does not represent a cash expenditure of \$20 per oz. Making allowance for this item, the cost could be reduced to 1.25c. per ton of solution, and even to 1c. per ton when working on a large scale.

The precipitation of the precious metals on zinc being so far perfected that solutions containing but a trace of cyanide and a few cents per ton in precious metals could be treated profitably, more attention was paid to a thorough and complete washing of the tank charges with fresh water.

It was known that in charges of from 25 to 30-mesh roasted ore containing 25% of material passing 200-mesh screen, the washing of the finer material was a difficult and tedious operation. On a large scale, I have used as much as 2 tons of fresh water per ton of ore in the charge, and in exceptional cases, 3 tons, exclusive of the residual water discharged with the tailings; while for the last three years my practice has been to pass through the charges not less than 1.5 tons of fresh water for each ton of ore, and where circumstances permitted, from 2 to 2.5 tons for each ton of ore.

This practice necessarily gave very weak terminal solutions, the final drains from the tanks seldom showing more than a trace of cyanide but not less than 3c. in gold per ton, unless the washing was carried up to or beyond two parts of water to one of ore. Hence complete washings are very important.

This work demonstrated further that fine and coarse ore, *i.e.*, from 50 to 150-mesh, should not be worked in tanks with ore below 200-mesh in either a dry or wet crushing process, and that quicker and better results can be obtained by working the infinitesimally fine ore separately from the coarser. Ores of 200-mesh can be as easily leached as ores of 30-mesh, if the usually light and flocculent material is removed that fills up the interstitial space between the 200-mesh particles, retarding or entirely preventing percolation. This light material is here designated as infinitesimally fine ore. By experiment it was found that the removal of the infinitesimally fine material in 150-mesh product to the extent of but 20%, rendered an impervious ore amenable to rapid percolation. I do not lose sight of the fact that in dry crushing, the fine and coarse ores are so well mixed that they are readily and cheaply leached together;

but I wish to go on record as stating that with ores of \$15 per ton gold value or upwards, better work can be done by removing the infinitesimally fine ore and subsequently treating the coarse and fine material separately.

Returning to the weak solution of wash water, while the final drains were about as given, the average solution passing to the precipitators was much richer, as it contained solution from tanks of various stages of completion.

The determination of the values in these low-grade solutions, in a quick, cheap and commercially accurate manner, gave at first quite a little trouble. The ordinary method of evaporating 1 or 2 assay tons in a lead tray, and then rolling up and cupelling the foil, did not give weighable results; for some time, therefore, we were forced to evaporate 500 c.c. of solution for each sample; a long and tedious process.

Experiments on various precipitants were taken up, zinc dust, which had proved so effective in large scale operations, being among the very first, but in this small way it was found wanting; however, on moistening the powdered zinc with lead acetate, and agitating for two hours, excellent results were reached. The method was used for several months. On further and more complete investigation, however, the following assay method for the zinc precipitation of gold in low-grade cyanide solution was adopted, which gave quick and perfectly reliable results, and was used for all low-grade solutions to the exclusion of other methods.

Take 500 c.c. of the solution to be assayed, or for greater convenience, prepare a measuring flask to hold 20 assay tons of the solutions. Take a tall beaker, add 7 g. of zinc dust, and pour in the 20 assay tons of solution; next add 10 c.c. of commercial sulphuric acid, stir well with a glass rod, and cover with a watch-glass. When the action begins to fall off, add a further 10 c.c. of acid. The precious metals will be completely precipitated in from 10 to 20 minutes, but the solution had best be left in the beaker till the zinc is practically dissolved, usually occupying 40 minutes. A smaller quantity of zinc should not be used, and if the gold and silver is over 0.05 oz. per ton, 10 g. should be taken.

When the action is completed, filter, add 2 g. of silica to the residue on the filter-paper, fold, place in a 10-g. crucible, incinerate in the muffle, remove crucible and when cool add 10 g. each of flux and litharge, thoroughly mix in the crucible; fuse, cupel, weigh and part in the usual manner. The flux used consisted of 42 parts potash, 84 sodium bicarbonate, 42 borax glass, and 9 of flour. Should copper be present in solution, a larger proportion of flux will be required, and scorification may be necessary. The solution on which this assay method was used varied from 0.100 to 0.001 oz. gold per ton, and from 0.035% to 0.005% KCN, though it can be used on any solution if sufficient zinc dust is added to precipitate all the precious metal present.

This assay method was tested against evaporation to dryness with litharge and assaying the residue, and with ordinary care was found to give most excellent results. A few of the tests made on 20 assay tons of solution are given on the following page. These tests are from daily routine work, and show that the assay by the zinc method is as safe and reliable as that by evaporation. Its advantages over the latter method are that it is more economical, both in time and expense, and requires less attention.

Mr. C. W. Merrill had some tests made with this zinc assay on solutions containing 0·03% copper which gave results several per cent. lower than the method in use at his works. Upon investigation the discrepancies were found to be due to losses subsequent to precipitation; when 10 to 20 assay tons of a solution carrying 0·8 oz. gold, and 0·4 oz. silver per ton were used, no trace of gold or silver was found to have escaped after evaporating and assaying the filtrate.

A series of assays was then made with the following results:—

| Method.            | Assay.<br>Tons. | Gold. |        | Silver. |         | Remarks.                                                            |

| Scorification..... | 8               | ·06   | 1·20   | ·325    | 0·16    |                                                                     |
| Evaporation.....   | 4               | ·06   | 1·20   | ·32     | 0·16    |                                                                     |

It will be observed that the correspondence between the methods is very close. More care, however, was taken with the tests than is usual in ordinary practice. The evaporation method was more rapid, but this may be partially accounted for by the fact that only 4 assay tons were used; moreover the operator was hampered by lack of conveniences for carrying out the zinc dust method.

Mr. Merrill states that the results marked "Argall" were obtained by precipitating 8 assay tons with 7 g. of imported zinc dust (2·75% lead), and adding two lots of 10 c.c. each of sulphuric acid, filtering as soon as the zinc was practically all dissolved, using a rapid filter-paper, washing twice (this is not necessary), sprinkling with 4 to 5 g. of silica, transferring to crucible and burning at low temperature. 40 g. of flux were used, two-thirds being mixed with the ash, etc., and the remainder used as a cover. The zinc dust scorifier results were obtained by precipitating and filtering exactly as before. 25 g. of granulated lead were taken; one-third being put in the bottom of a 2·5-in. scorifier and one-third sprinkled over the filter-paper and precipitate, which was folded and covered in scorifier with the remaining lead. This was then dried at the muffle door and scorified for 10 minutes. The evaporation results were obtained by evaporating 4 A.T. to one-third bulk in a stoneware saucer, adding 70 g. of mixed flux (litharge 48, silica 20, charcoal 1·8), drying, mixing with 14 g. of soda ash, wiping out saucer with filter-paper moistened with dilute nitric acid, and adding this with a little litharge on top of charge, which was melted 25 minutes.

Mr. C. A. Hoyt, who used this zinc-dust assay method for some time, gives the following details as to results:—

The filtration from the zinc precipitate was conducted in 15 funnels over a

V-trough which led out of the building, this being the quickest way to filter. For 20 assay tons of the solutions a slightly heaped teaspoonful of zinc dust and about 10 to 15 c.c. commercial sulphuric acid were used. The actual precipitation is probably completed within 15 minutes, but it is better to let nearly all the zinc dissolve before starting to filter. The time required for handling 15 solutions was about four hours, as follows: Precipitation, 40 minutes; filtering, 30 minutes; burning filter and precipitate in muffle, 10 minutes; cooling crucible and fluxing same, 30 minutes; fusion in hot furnace, 30 minutes; slagging and cupelling, 40 minutes; parting and weighing, 60 minutes. This is a rough estimate of the average time required for 15 solutions, and no doubt the time could be shortened with better facilities.

The assay method is here published with the hope that it may prove as useful to others as it has to myself for rapidly and accurately determining the gold and silver contents of low-grade cyanide solutions.

#### REVIEW OF ANALYTICAL CHEMISTRY OF GOLD AND SILVER DURING 1901.

BY EDMUND H. MILLER.

THE detection of small quantities of gold and silver is described by Luther Wagoner<sup>1</sup> giving methods of determining infinitesimal quantities of gold and silver by cupellation and measuring the bead by the microscope and calculating its weight from the diameter. Tested in this way ordinary assay reagents, as sodium salts, acids, lime, borax, etc., all contained silver, while potassium cyanide showed both gold and silver.

A variety of rocks, as granite, sandstone, syenite, marble, etc., contained both gold and silver. Gold, from 21 to 1,130 mg. per 1,000 kg.; silver, from 201 to 15,430 mg. per 1,000 kg. In sea water gold was found to the extent of 11.1 mg. per metric ton, or about \$0.0067 per ton of 2,000 lb.

Prof. Richards of Lehigh<sup>2</sup> describes the measurement of gold and silver buttons obtained by quantitative blow-piping by a new kind of scale. "The idea is to make two metallic edges, perfectly straight, lying on a flat surface, touching each other at one point and held apart at the other extremity by a set-screw; so that the point 100 may indicate a fixed width or separation of almost exactly 1 mm." In using the scale the button is put into the groove, the scale inclined slightly and tapped until the button wedges itself, and the diameter read off on the scale to tenths of a millimeter. For further directions and the necessary tables the original article must be consulted.

E. A. Smith<sup>3</sup> has collected and reviewed the best methods for assaying of complex gold ores. With a few exceptions, which are brought out in the discussion printed with the article, the article presents recent American practice, and is useful for students, as it gives an excellent résumé of the methods for certain ores. It contains nothing new to American assayers.

Holborn and Day<sup>4</sup> give the melting point of pure gold as 1,063.5°C.

<sup>1</sup> Paper read before the American Institute of Mining Engineers, November, 1901.

<sup>2</sup> *Journal of the American Chemical Society*, April, 1901, p. 203.

<sup>3</sup> *Transactions of the Institution of Mining and Metallurgy*, Vol. IX., p. 315-61.

<sup>4</sup> *American Journal of Science*, February, 1901.

L. W. Andrews<sup>5</sup> has devised a new method for the titration of silver by the use of iodide of starch solution, as originally proposed by Pisani, but under entirely different conditions, as the reaction takes place in a nitric solution in the presence of both ferrous and ferric salts. The reaction is as follows:—

The end point is the blue of the standard solution, so no other indicator is required, and in this respect the method has the same good feature as potassium permanganate. Preparation of the solution—50 g. of washed starch are rubbed up with 8 or 9 g. of sublimed iodine, and the mixture with 100 c.c. of water, is transferred to a wide tube of heavy soft glass, sealed and heated for several hours in boiling water; then diluted and filtered through a hardened paper. From this solution N/20, N/50 or N/100 solutions can be prepared by dilution. The strength of the solution must be determined by titration against silver and not against sodium thiosulphate for a portion of the iodine present is in a condition (analogous to an alkyl iodide) which reacts with silver but not with thiosulphates.

The conditions for titration are as follows: The solution is to be acid with nitric acid, but must not contain over 5% chlorides, bromides, iodides, cyanides, thiocyanates; also, mercury salts and arsenic or antimony in the triad condition must not be present. Sufficient ferrous sulphate or nitrate must be added so that the iron present will equal the silver; then an equivalent quantity of the same ferric salt. An excess of iron salts is without influence. When very small amounts of silver are present (less than 20 mg.) the sulphates can be used, but if a considerable quantity of silver is to be determined, nitrates must be used to avoid the formation of silver sulphate. The iron salts are best kept in the form of sulphates, and before use converted to nitrates by a measured excess of lead nitrate. The titration should be made slowly with stirring in a casserole to give a white background. The end point is so sharp that variations in dilution are practically without effect. Copper and lead nitrates have no influence on the results.

For the determination of large quantities the author recommends that most of the silver be precipitated by sodium bromide, and the filtrate titrated by the iodide of starch method. The only drawback to this method seems to be the trouble of preparing the standard solution, and even though it does not displace the familiar and well proven methods of Gay Lussac, Mohr, and Volhard, it represents in its development an excellent piece of chemical work.

R. G. van Name<sup>6</sup> shows that while silver thiocyanate is not suitable as a means of determining silver gravimetrically on account of its solubility in an excess of alkali thiocyanates, yet it is an excellent means of estimating thiocyanic acid, by using an excess of silver nitrate, filtering on a Gooch crucible, and drying at 115°C.

A. Hollard<sup>7</sup> describes a method for the determination of silver in ores such as galena—by dissolving in nitric acid, etc., then electrolyzing from a cyanide solution, and finally titrating by Volhard's method and states that it can be applied to crude copper. Scorification seems simpler.

## GRAPHITE.

THE production of crystalline graphite in the United States during 1901 amounted to 3,967,612 lb., valued at \$135,914, as compared with 4,103,052 lb., valued at \$164,122 in 1900. As in previous years, the mines in the Ticonderoga district, N. Y., produced the greater part of the output, although the mines of Chester County, Pa., and Barton County, Ga., contributed considerable quantities. The mine in Clay County, Ala., which was inoperative during 1900, produced approximately 150 tons of crude graphite during 1901. The production of amorphous graphite in the United States during 1901 was 809 short tons, valued at \$31,800. Under this head is included the so-called graphitic anthracite of Rhode Island, which is of structure between scaly and granular and contains as much as 52% C in selected samples, and the so-called Baraga graphite of Michigan, which in reality is a carbonaceous schist. In addition to the production stated above there has been considerable activity in developing graphite mines in South Dakota, Georgia, Montana, New Jersey and North Carolina, and in the aggregate some 25,000 tons of material has been mined and is awaiting the selection of proper concentrating processes to convert the product into salable form.

### THE PRODUCTION, IMPORTS AND CONSUMPTION OF CRYSTALLINE GRAPHITE IN THE UNITED STATES.

(a) Production of refined graphite only; of amorphous graphite there were produced 1,200 tons (\$11,400) in 1897, 1,800 tons (\$11,400) in 1898, 1,080 tons (\$8,240) in 1899, 1,045 tons (\$8,640) in 1900, and 809 tons (\$30,800) in 1901. (b) Nominal.

Special interest has been attracted to the mineral graphite in recent years, due to its increased domestic production, prices and importation. For a long time

curious prejudices existed which hampered the development of the industry, and considerable confusion frequently resulted from the different names which have been used to designate the mineral—plumbago, black lead, pot lead, etc. Latterly the high prices of graphite and the small supply have done much to remove these prejudices, and the advent of artificial graphite, together with the attempt to market a variety of grades of graphite from new prospects have helped to develop the industry. The bulk of the supply of the best grades of graphite continues to be obtained from Ceylon, and probably amounts to from 75 to 80% of the total consumption of the United States. The great activity in the metal trade during the past few years has resulted in the increased consumption of crucible graphite and other high grades, which has been further augmented by the increased use of graphite as a paint pigment, as a lubricant, and in electrical work: for the last-named use no substitute for graphite has yet been found. The demand for a lubricant which will withstand the heat due to high pressure and high speed has led to the use of graphite, which fulfills these requirements. In December, 1901, United States Patent No. 697,996 was allowed to Mr. W. F. Downs, of Jersey City, N. J., for a lubricant consisting of particles of a solid lubricant coated with an oil in which it is insoluble and suspended in an enveloping oil with which the coating-oil is not miscible, which promises to increase largely the consumption of graphite for this purpose.

The preservation of the life of steel structures has demanded the attention of the civil engineers, and at many of the meetings of the engineering societies interested in structural iron work papers have been read during the past few years of the various means of prolonging the life of steel structures. The consensus of opinion is largely in favor of a carbon or graphite pigment in the paints or coatings used, and, as a consequence, the manufacture of graphite paint, using as a raw material the amorphous graphite from certain deposits in Michigan or the artificial product from the electric furnace, has been very greatly increased.

*Alabama.*—The Allen Graphite Co. operated a mine in Clay County, and was the only producer during 1901. The Alabama Graphite Co., with mines in Cleburne County, reported no production.

*Michigan.*—The Hathaway Graphite Manufacturing Co., with mines at L'Anse, Baraga County, reported an increased output of amorphous graphite for 1901; the product is of low grade and suitable for foundry facing, paint, and similar uses.

*Montana.*—The Crystal Graphite Co. shipped a few sample lots of graphite ore East, from its mines near Dillon, to test its suitability for crucible manufacture. The product is crystalline and of high grade, closely resembling the Ceylon variety.

*New Hampshire.*—The American Graphite Co. is reported to be erecting a refining plant at its mines in Merrimac County. A tunnel 120 ft. in length has been driven at the principal mine.

*New York.*—In the northern part of the State graphite occurs in schistose rock and, while seldom carrying more than 10% of mineral, it yields by far the greater part of the output of crystalline foliated graphite production of the United States. The production of graphite during 1901 from the two mines

owned by the Joseph Dixon Crucible Co., located at Graphite and Hague, near Lake Ontario, has not changed materially from that of the previous year. The mine and plant at Buck Landing, near Ticonderoga, and a plant at Johnsburg, N. Y., which began operations in 1900, were shut down owing to an insufficient supply of ore. The mine and plant at Pottersville is being enlarged and developed by the International Graphite Co., but the presence of a continuous and paying ore body has yet to be demonstrated. Gray Brothers, at Ticonderoga, have a promising prospect at Rock Pond, midway between it and Schroon Village; though little development has been done, surface outcroppings indicate a considerable body of low-grade ore. This property will be further exploited by a recently organized company.

*Pennsylvania.*—The only concern reporting a production of graphite during 1901 was the Philadelphia Graphite Co., whose mine is situated a mile east of Chester Springs, Chester County. The mineral occurs in two layers of disintegrated mica schist respectively 4 ft. and 6 ft. in thickness. In mining the drifts are run in on the hillside following the layers; the rock is so disintegrated that most of the graphite material can be removed with the pick and shovel without the aid of blasting. At the mill the ore is crushed in rolls and cleaned in a washer similar in principle to the common washer used at clay works. After washing it is again ground and further refined by means of air currents and separated into different grades. At another point, Byers, at the end of the Pickering Valley branch of the Philadelphia & Reading Railway, several miles below Chester Springs, graphite has been mined in considerable quantities in recent years. The ore is of a low grade and has been shipped to Reading and Bethlehem for use as a foundry facing. The graphite works at Byers were destroyed by fire in 1900. At Pikeland, Chester County, there is an abandoned graphite mine and refining plant which was productive a few years ago. Near Mertztown, in northern Berks County, a graphite mine and refining mill have been operated at intervals during the past 20 years, but no production was reported in 1901. The graphite occurs in a lenticular vein in a coarse-grained sandstone of a maximum thickness of 39 ft., which is mined with pick and shovel in galleries at different levels; 28% of the mined material is graphite. At Boyertown, in eastern Berks County, an abandoned graphite mine was re-opened in 1899 by the Boyertown Graphite Co. and a refining mill erected. The works, however, were not successful financially. Graphite occurs at other points in Pennsylvania, but, so far as is known, it has not been produced commercially except at the mines mentioned.

*Rhode Island.*—The Rhode Island Graphite Co. reports an increased output during 1901 from the mine at Arlington. The amorphous product variety is principally used as a foundry facing and for the manufacture of polishes.

*South Dakota.*—The graphite mine near Custer, Custer County, which yields a product stated to contain from 26 to 41% C, has not been developed owing to the low grade of the material and the cost of shipment to market.

*Other States.*—Several deposits of amorphous graphite have been reported from California, Colorado, and Texas. None of these, however, have as yet been proven of high value.

## WORLD'S PRODUCTION OF GRAPHITE. (IN METRIC TONS.)

| Year. | Austria | Canada | Ceylon.<br>(d) | Germany. | India. | Italy. | Japan. | Mexico | Russia. | Spain. | Sweden | United States.<br>(b) | Total.  |
|-------|---------|--------|----------------|----------|--------|--------|--------|--------|---------|--------|--------|-----------------------|---------|
| 1896  | 35,072  | 126    | 10,463         | 5,248    | (a)    | 3,148  | 215    | 620    | (a)     | Nil.   | 14     | 184                   | 55,388  |
| 1897  | 34,504  | 596    | 19,275         | 3,801    | 61     | 5,050  | 204    | 907    | (a)     | (a)    | 99     | 450                   | 60,311  |
| 1898  | 33,002  | 1,107  | 78,508         | 4,593    | 22     | 6,435  | 346    | 1,857  | 98      | 10     | 50     | 834                   | 125,708 |
| 1899  | 31,819  | 1,105  | 29,057         | 5,196    | 1,548  | 9,990  | 35     | 2,305  | 29      | (a)    | 535    | 1,648                 | 80,008  |
| 1900  | 33,009  | 1,743  | (c)            | 9,249    | 1,868  | 9,720  | 94     | 2,561  | (c)     | (a)    | 84     | 1,562                 | 58,770  |

(a) Not reported in the government statistics. (b) Crystalline graphite. (c) Statistics not yet published. (d) The figures for 1897 and 1899 are exports; the enormous production in 1898 as reported in official government publications is not reflected in the exports for that year, which amounted to 24,349 metric tons.

*Austria.*—With regard to the genesis of graphite deposits, those of upper Styria, according to K. A. Redlich, are of sedimentary origin, which does not agree with the heretofore accepted opinion of Dr. Weinschenk that they are of contact metamorphic character. The graphite occurs in two forms, the one soft and flaky and the other hard and crystalline; both are found in the conglomerate near Truben; although the hard variety only occurs in the beds which have been folded or bent. Mr. J. L. Barvir refutes Weinschenk's theory that the graphite of southern Bohemia was formed by gaseous emanations containing carbon monoxide and offers the theory that it was derived from organic origin.

*Canada.*—The production of graphite during 1901 was 2,190 short tons, valued at \$44,380, which was derived mainly from the Black Donald mine, at Brougham, Renfrew County, Ont. Owing to the distance from the railway the product can only be shipped to market during the winter. This deposit is of unusual size and is being developed 12 miles west of Calabogie station on the Kingston & Pembroke Railroad. The workings consist of open cuts and a shaft 80 ft. deep, from the bottom of which a drift on the vein extends 150 ft. northeast, going under Whitefish Lake. The vein stands vertically and at a depth of 80 ft. measures 22 ft. in width. The enclosing country rock on both walls is limestone. Hoisting is still done with a derrick and a 2-ton hoisting engine. Since opening the mines 4,000 tons of graphite have been shipped, of which about 1,800 tons represent the output for 1901.

*India.*—In the Ceylon deposits the graphite occurs in typical symmetrical veins, although crushed and altered by earth movements which have spent their energy upon the soft graphite and have consequently spared the granulite country rock. Weinschenk concludes that the graphite is of volcanic and not of organic origin, due, in all probability, to the action of vapors carrying carbon. He offers the suggestion that carbon dioxide and cyanogen compounds have played the chief part in its production. Among the associated minerals it is remarkable that, as at Passan, nontronite is one of the invariable decomposition products accompanying graphite.

The decline in the value of graphite has checked mining operations and many of the smaller mines have been abandoned. The larger pits yielding better qualities, and those of wealthy owners employing skilled European supervision, showed an increased output and prospered fairly. In Kurunegala only 50 plumbago pits were worked in 1900, as compared with 151 in 1899, and in the southern province only 30 acres were leased as against 117. A graphite mine 14 miles from Trivandrum, in Travancore, is worked by Cornish miners, and turns out more than 100

tons of graphite each month. The export of the mineral from Travancore in 1900 was 1,600 tons. Mr. T. L. Walker reports the occurrence of graphite in several localities in N.E. Kalahandi State. The deposits are in parallel beds and apparently of good quality. About 40% of the Ceylon product is imported into this country, approximately the same amount goes to England, while Europe takes the remainder. The Ceylon graphite that comes to America is imported directly by steamer in packages of a net weight of about 600 lb. each. It is graded in the order of its value into "lump," "chip," and "dust" graphite. The first grade consists of the larger and softer pieces, the second, as is indicated by its name, is made up of smaller lumps and fragments, while the dust graphite, the lowest in value, carries the bulk of the earthy impurities. These grades again are subdivided according to their brightness, or "boldness," the term used in the trade, and softness. The importations of European graphite into America is far less, relatively to the amount produced, than that from Ceylon, for the reason that for many of the uses to which the amorphous variety is put in Europe the domestic product has been substituted in the United States. While, of course, it is impossible to apportion with accuracy the relative amounts of graphite applied in its various uses, they are approximately as follows: In crucibles, 55%; stove polish, 15%; foundry facings, 10%; paint, 5%; lubricating, 5%; all others, 10%. The last item includes graphite for powder glazing, electrotyping, steam packing, and various minor uses.

*Mexico.*—A very fine variety of pencil graphite is mined at Torres, Mex., by an American company.

#### ARTIFICIAL GRAPHITE.

The manufacture of crystalline and amorphous "artificial graphite" by the sole producer, the International Acheson Graphite Co., at Niagara Falls, N. Y., has increased enormously, as is shown by contrasting the production in 1901 of 2,500,000 lb. with 860,750 lb. in 1900, and 105,870 lb. in 1899. Graphitized electrodes used in the electrolytic production of alkali and bleach consumed more than one-half of the output in 1901, while paints, pencils, lubricants, motor brushes, crucibles, and dry batteries absorbed the balance of the production.

#### PRODUCTION AND VALUE OF ARTIFICIAL GRAPHITE FROM 1897 TO 1901, INCLUSIVE.

| Year.     | Pounds. | Value.   | Unit Value per Pound. | Year.     | Pounds.   | Value.   | Unit Value per Pound. |
|-----------|---------|----------|-----------------------|-----------|-----------|----------|-----------------------|
|           |         |          | Cents.                |           |           |          | Cents.                |
| 1897..... | 162,282 | \$10,149 | 6.2                   | 1900..... | 860,750   | \$68,860 | 8.0                   |
| 1898..... | 185,647 | 11,608   | 6.2                   | 1901..... | 2,500,000 | 119,000  | 4.75                  |
| 1899..... | 105,870 | 32,475   | 8.0                   |           |           |          |                       |

The decrease in the unit value of the total production from 8c. per lb. in 1899 and 1900 to 4.75c. per lb. in 1901 was largely due to the increased proportion of the amorphous variety produced.

The furnaces used in the Acheson process for making graphite and graphite electrodes commercially are similar to those used in Acheson's process for making carborundum (silicon carbide). They are built of brick in the form of a long, narrow trough lined with suitable refractory material. Graphite electrodes are

manufactured of petroleum coke and pitch like an ordinary carbon for arc lights, but a certain amount of some carbide-forming material, as silica or iron oxide, is introduced. The electrodes after baking are graphitized in a furnace heated to a temperature well above that of the volatilization of iron, aluminum and silicon and similar elements. That the temperature used in the Acheson furnaces is well above the volatilization point is demonstrated by the fact that the elements above named are condensed as oxides outside the furnace.

Anthracite coal is usually employed in manufacturing graphite for crucibles, paint, stove polish, etc. The furnace is filled with anthracite coal through the center of which runs a core composed of a carbon rod connecting the terminals of the furnace electrically. When cold, anthracite coal is a very poor conductor of electricity, hence the necessity for the core, which acts as a conductor and heats the surrounding anthracite when the furnace is started. Finally, the whole mass is raised to a very high temperature and converted into graphite. On cooling, the latter is removed from the furnace and ground to the desired fineness. The physical change produced by the Acheson process for manufacturing graphite electrodes is illustrated by the following table:—

| Amorphous carbon electrodes:          |              | Graphite electrodes:                  |               |
|---------------------------------------|--------------|---------------------------------------|---------------|
| Density.....                          | 1.90 ohm.    | Density.....                          | 2.19 ohm.     |
| Electrical resistance per cu. in..... | 0.00124 ohm. | Electrical resistance per cu. in..... | 0.000820 ohm. |

The high temperature volatilizes nearly all of the contained impurities, leaving from 0.1 to 0.5% ash. The electrodes show marked resistance to disintegration in the electrolysis of sodium chloride solutions, having from 2 to 3 times the life of the most resistant form of amorphous carbon (retort carbon) and from 3 to 7 times the life of artificial carbon anodes. Tests made on the graphite produced from anthracite show that it is free from amorphous carbon. The average product of the furnaces contain approximately 5% of ash, and is therefore far purer than the average natural graphite. When necessary, purer graphites are produced by heating to a high temperature for a sufficiently long time to volatilize and drive off all impurities. Anthracite treated in this way produced a graphite containing only 0.31% of ash, although the original coal carried about 15% ash. This small quantity of residual ash is undoubtedly due to the condensation of the vapors existing in the furnace when the current is cut off. Mr. Acheson has considered a plan by which these may be washed out during the operation of the furnace by the use of nitrogen or other inert gas, but commercial requirements have not as yet necessitated putting this into practice.

It is a remarkable fact that in spite of the large amount of work that has been performed by various experimenters on the conversion of amorphous carbon into graphite, half a century elapsed before a process was developed commercially. Over 50 years ago, with a battery of 600 Bunsen cells, Duprez attacked this problem; but it was only within a few years that a method was discovered which, with the electric current at Niagara Falls, produced in 1901, 2,500,000 lb. of graphite from artificial amorphous carbon.

Acheson artificial graphite electrodes are recommended for electrolytic and electro-metallurgical processes, the advantages claimed for them being long life, low porosity, high conductivity and great economy. The electrodes are made by

treating in the electric furnace amorphous carbon articles made up in the shape desired. The product is stated to be entirely free from amorphous carbon, and the percentage of impurity in the finished electrodes is given as 0.1%. The size of the electrodes is limited generally by the difficulties of manufacture. In rectangular shapes the cross section is limited to about 28 sq. in., and the length to 36 in. The width of a carbon is usually limited to 8 in. In round carbons the length is limited to 36 in., and the diameter is 5 in. These limits can be increased slightly when large amounts are ordered. Some striking results have been obtained in tests made in Germany with Acheson graphite electrodes in the electrolysis of sodium chloride solutions.

## GYPSUM.

THE production of gypsum in the United States continued to increase greatly during 1901, the output amounting to 659,659 short tons, valued at \$1,577,493, as compared with 484,202 short tons in 1900.

The increase in the production of gypsum in the United States during recent years has been remarkable. For the ten years previous to 1899 the annual output averaged a little more than 250,000 short tons, which has risen to the maximum output of 659,659 short tons in 1901. This rapid development has resulted mainly from two causes, one the increased use of plaster of Paris in the manufacture of wall plaster in modern buildings, and the other to the large quantities consumed in the manufacture of staff for the construction of temporary buildings, particularly those built for exposition purposes.

(a) From official reports of the respective countries, except the statistics for the United States. (b) A part of the product is reported as plaster of Paris. In converting this to crude gypsum it has been assumed that the loss by calcination is 30%. (c) Prussia is a large producer of gypsum, but there are no complete statistics available. (d) Statistics not yet available.

## THE GYPSUM CEMENT PLASTER INDUSTRY IN KANSAS DURING 1901.

BY E. HAWORTH.

EARLY in 1901 the American Cement Plaster Co. purchased the mills of the Salina Cement Plaster Co., at Dillon and Longford, closing the former. In June this company shut down the mill at Mulvane and later acquired the plant of the Great Western Co., at Blue Rapids. About two years ago the American Cement Co. bought a large tract of gypsum land at Acme, Tex., and is operating a large mill there, and in February, 1902, it acquired additional gypsum land in Indian Territory. In April the Sampson Cement Plaster Co., at Burns, was sold to A. D. Macky, who continued to operate the plant under the old firm name with offices at Burns. In the latter half of the year, the Alumanite Co., with mills near Dillon, was re-organized under the name of the Aetna Cement Plaster Co., and its mills put in operation. The Kansas Cement Plaster Co. changed its name to the Wymore Cement Plaster Co., with offices at Wymore, Neb. The Roman Cement Plaster Co. continued operation near Springvale throughout the greater part of the year.

Early in 1902 a general change was effected by the formation of the United States Gypsum Co., capitalized at \$10,000,000, with offices at Omaha, Neb., which in addition to the works in Kansas, consolidated the following companies:—

*Iowa.*—Baker Plaster Co., Carbon Plaster Co., Cardiff Gypsum Plaster Co., Duncombe Stucco Co., Fort Dodge Plaster Co., Iowa Plaster Association, Mineral City Plaster Co., all of Fort Dodge.

*Kansas.*—Great Western Cement Plaster Co., Blue Rapids Cement Plaster Co., of Blue Rapids; Roman Cement Plaster Co., of Kansas City, and Blue Valley Plaster Co., of Omaha, Neb.

*Michigan.*—The Alabaster Co., of Alabaster; the Alabastine Co., Grand Rapids Gypsum Works, Gypsum Products Manufacturing Co., Michigan Plaster Co., Midland Plaster & Cement Co., all of Grand Rapids; New Buffalo Alabastine & Mineral Paint Mfg. Co., of Lansing; John McPhee, of Nelson; and Durr Plaster Co., of Grandville.

*New York.*—English Plaster Works, Otto B. English Plaster Co., Genesee Stucco Works, Big Four Plaster Co., all of Oakfield, N. Y.

*Oklahoma.*—Oklahoma Cement Plaster Co., of Okarche.

The Western mills not belonging to the United States Gypsum Co. are the American Cement Plaster Co., the Best's Keen Cement Co., at Medicine Lodge, and the Acme Cement Plaster Co., at Quanah, Tex., and Laramie, Wyo., Samson Cement Plaster Co., Burns, Kan., Aetna Cement Plaster Co., Kansas City, Mo., and Dillon, Kan., Best's Keen Cement Plaster Co., Medicine Lodge, Kan.

*Technology.*—The methods of handling gypsum and its products have not changed materially during the last few years. Rock gypsum is quarried similar to the methods followed for stone or coal, and the rock is crushed and calcined into plaster of Paris. Gypsum earth is taken directly from pits to calcining kettles and calcined, the difference in treatment being due to the physical structure; one is a rock, while the other is loose like sand. At Blue Rapids, quarrying is done at each of the three mills by tunneling or drifting into the bluffs, the rock being mined by the double-room and pillar system. Tramways are

laid, and the quarried rock carried by cars hauled by cable or other power. At the Great Western mine, the ground cars are drawn directly into the mill and the rock gypsum dumped beside the crusher. At Hope a shaft is sunk 80 ft. to the rock gypsum, which is hoisted to the surface, loaded on cars and drawn by the local freight engine to the mill a quarter of a mile away. At Medicine Lodge, gypsum occurs on high hills about 5 miles S.W. from the city where the factory is located. The rock gypsum is quarried from the hill tops in a manner similar to the general quarrying of building stone and hauled by team to the factory, where it is crushed and calcined.

Crushing at most of the mills is done by some modified form of the jaw crusher, which reduces the gypsum to a small size; it is then ground to a fine powder by the old-fashioned stone burrs formerly used in flouring mills. The Kansas mills use machinery manufactured at Enterprise or Leavenworth, Kan., or Grand Rapids, Mich. A few years ago Grimsley<sup>1</sup> gave a very good description of the machinery and other appliances used in Kansas. No changes of importance have been made since his report was published. The lime disintegrator manufactured by the Stedman Foundry and Machine Works of Aurora, Ind., has not yet been introduced into Kansas, although it is extensively used in Michigan and by the Western Plaster Works of Chicago.

The general method of handling gypsum earth is to remove the overburden by plow and scraper, as in railway grading, and loosen the gypsum earth by driving over it in different directions with an ordinary farmer's disc harrow, later using a horse scraper to haul the material to the mill. Detailed operations differ in various localities, depending upon the relative location of the mill and the pit.

Calcining is universally done by means of the old-fashioned kettle, which is described and illustrated in the article by Grimsley, already quoted. Crushed rock gypsum or gypsum earth, is placed in the kettle and heated to the proper temperature to drive off a part of the water of crystallization, the material being moved by mechanical agitators. When half the water of crystallization has been driven off, it is pronounced "done," a valve is opened and the calcined gypsum powder runs out by gravitation into a chamber having masonry walls, where it is allowed to cool. In a few mills, as the ones at Mulvane, Kan., and Marlowe, Ind. Ter., the calcined material is immediately elevated by suction power, a process which not only elevates the plaster to the proper chambers but cools it at the same time. In other mills the elevating is done by chain buckets which, while cheaper to operate, requires more time and does not have the advantage of properly cooling the plaster. The suction method is expensive in that a large amount of power is required for a short time only, necessitating a much larger steam capacity than that required for the slower bucket elevator.

The plaster, after elevating, is mixed with proper amounts of a retarder and fiber. The general practice is to use a patented mixer consisting of a hopper for the reception of the plaster, which feeds into a cylinder where it is thoroughly mixed and forced out by an auger. From the mixer it is taken to bins and finally put into bags or barrels on the lower floor, the plaster passing down through wooden pipes or conduits from the bins above in a manner similar to the grain conduits in grain elevators.

## IRON AND STEEL.

**DURING 1901** the production of pig iron was 15,878,354 long tons, against 13,789,242 long tons in 1900, an increase of 2,089,112 long tons during the year. Despite this enormous increase in production which was only slightly exceeded by the production of 1898 against that of 1897, the active demand for iron and steel was such at the close of the year that iron and steel works of all kinds found difficulty in securing deliveries of pig, and importations of foreign pig were not unusual, more especially on orders from the Atlantic seaboard. Among the new plants begun in 1901 which will be completed in time to increase the pig iron output of 1902 are the following: A new 100-ft. stack for the Port Oram, N. J., works owned by Joseph Wharton, of Philadelphia, Pa. (A third furnace of the same size is to be added during 1902.) The St. Clair Steel Co., one of the subsidiary companies of the Crucible Steel Co. of America, is erecting an open-hearth steel plant at Clairton, Pa., and the St. Clair Furnace Co. is building three 500-ton blast furnaces at the same place. The steel will be absorbed by the Crucible Steel Co., and the plants are expected to be in operation about the middle of 1902. The completion of the new "B" furnace for the Iroquois Iron Co., on the Calumet river, South Chicago, Ill., during the latter part of 1901 makes the total daily capacity of the plant about 500 tons of pig iron. The plant is equipped with storage capacity sufficient to permit its annual ore supply to be brought down during navigation season, and the strongly built docks and eight Brown hoisting and conveying machines permit two vessels to be unloaded simultaneously at the rate of 400 tons of ore per hour. The stock ore piles are situated close to the furnaces to avoid rehandling. The plant was designed by Julian Kennedy, of Pittsburg, Pa. The new Searles furnace of the La Follette Coal, Iron & Railroad Co., of La Follette, Tenn., is expected to be blown in by July, 1902. Its capacity is about 100,000 tons per annum. The Pioneer Furnace, of the Republic Iron & Steel Co., with a capacity of about 100,000 tons per annum, at Birmingham, Ala., was started in April, 1902. In Alabama the Central Iron & Coal Co., at Tuscaloosa, is erecting a coke blast furnace and three other stacks whose product is not expected to be available during 1902 are also under construction elsewhere in the State. The Lackawanna Steel Co. has moved its Scranton plant, comprising two small stacks, to Buffalo, N. Y., and is adding two large modern stacks. Five large stacks are under construction in Ohio. Two new

---

large blast furnaces for the Colorado Fuel & Iron Co., at Pueblo, Colo., are expected to be blown in by the fall of 1902. The capacity of the two new stacks is rated at 275,000 tons per annum. The new Pioneer charcoal furnace under construction at Marquette, Mich., will be in operation in the fall of 1902. With the nine blast furnaces expected to be started during 1902 and the 18 furnaces at present under construction to contribute to the output of 1903, a considerable increase in pig iron production may be expected by the end of 1903.

The returns from the census of 1900 show, according to the list of selected manufactures prepared by the Bureau of Manufactures, that the Textile industries took first place in the list with a value of product aggregating \$966,924,835, but if the metallurgical industries, including iron and steel, lead, copper, and zinc, are taken together, as is the custom with textile industries, the product of the metal industries aggregates \$1,194,545,506 in value for the year 1900. Among separate industries iron and steel is far in the lead. The total number of men employed was 226,161, who received \$122,710,193 in wages. The rolling mills and steel works led the list with 183,023 men employed at wages aggregating \$102,238,692, against 39,241 blast furnace men earning \$18,484,400. A comparison of the numbers of plants operative in 1900 with those of 1890 shows the following: Including 57 plants making tin and terne plates there were in 1900, 725 operative plants, against 719 in 1890, a gain of 6 plants; 438 operative rolling mills and steel plants, as against 395, a gain of 43 plants; 223 operative blast furnaces, against 304, a loss of 81; 7 active forges and bloomeries, against 20, a loss of 13 plants for the decade. The capital invested in the 725 active establishments in 1900 aggregated \$580,041,710; \$122,710,193 was paid in wages; 9,544 officers and clerks were paid \$12,028,811; cost of materials used for conversion was \$549,127,082; miscellaneous expenses amounted to \$32,570,556. The total value of the manufactured produce was \$835,759,034, divided as follows: Rollings mills and steels works, \$596,588,034; blast furnaces, \$206,756,557; tin and terne plate, \$31,892,011; and forges and bloomeries, \$522,432.

The year 1902 has thus far developed no reaction from the very favorable trade conditions. The consolidation of the greatest iron ore producers, blast furnaces, and finishing works into the United States Steel Corporation, has probably more than any other one factor contributed to the steadying, both of prices and demand for iron and steel, and its settled policy of holding to the fairest range of prices in spite of the temptations formerly yielded to by smaller concerns to take advantage of restricted supply and increased demand, cannot but be of the greatest possible service to industry generally.

More than one-half of our structural steel is consumed in satisfying the demands for high bridges and structural steel work of tall buildings. The pressed steel car industry has attained to enormous proportions and demand is constantly increasing. Mr. James M. Swank, in *Statistics of the American Iron Trade for 1901*, states that: "It may not be generally known that our steam and trolley railroads consume in rails, cars, locomotives, bridges, buildings, and electrical machinery fully one-third of all the iron and steel we annually make. The building of steel vessels also calls for an increasingly large supply of steel plates and for steel in other forms." With increased railroad facilities

and the number of new stacks constructed during 1901, there is little foundation for the apprehension expressed so freely toward the close of the year, that large importations of iron and steel from abroad would be necessary to satisfy home demands for the crude product during 1902.

Our iron and steel exports for 1901 amounted to \$102,534,575 in value, against \$129,633,480 for 1900, showing a loss of \$27,098,905 during the year. Our imports of iron and steel were valued at \$20,394,995 during 1901, against \$20,443,911 in 1900. So much of the product of pig iron was consumed at home during the year that the decline in the value of exports of iron and steel is accounted for by the decrease in pig iron shipments. The exports of pig iron during 1901 amounted to 81,211 tons, against 286,687 tons in 1900.

The first report of the United States Steel Corporation confirms the great advantages claimed for the consolidation at the time it was organized in April, 1901. It has been deemed advisable to have the official year correspond with the calendar year, and this preliminary report covers only the first nine months of the corporation's existence. This period has been rather short to organize and systematize satisfactorily the large and diversified business interests in-

involved, yet the results even in this time have been more than gratifying. Great economies have resulted from the harmonious co-operation in the departments of ore mining, coal mining and lake transportation. The most pronounced benefits, however, have resulted from the manufacture of the various products at the point most favorable to the production, together with the greater efficiency of the work which has resulted from the free interchange of news and experience of all engaged in the various branches of manufacture. The net earnings of the corporation for the nine months ending December 31, 1901, after deducting current renewals and ordinary repairs for maintenance of plants, amounted to \$84,779,298, from which the following amounts were charged: \$2,250,000 to set aside as a sinking fund to retire the bonds of the corporation and subsidiary companies; \$11,400,000 for nine months' interest on the bonds of the corporation; \$26,750,000 dividends on the preferred stock at 7% per annum; \$15,227,000 dividends on the common stock at 4% per annum, making a total of over \$53,000,000. Nearly \$10,000,000 was set aside in various reserve funds to cover exhaustion of ore supplies, depreciation of machinery and special enlargements. The above shows individual earnings of over \$19,000,000 for the nine months' operations. A balance sheet showing the assets and liabilities at November 31, 1901, is included in the report in place of a detailed profit and loss statement, which latter cannot be given satisfactorily until absolute uniformity in the accounting systems of all the companies has been established. In brief this report will be found on page 381.

It is stated that the actual business booked of which shipment is being called for faster than it can be supplied, amounts to more than half the total combined annual capacity of all the companies and the heavier products as rails, billets, plates and structural shapes are sold up to the productive capacity of the mills until nearly the end of the year. Despite the great demand for products the prices have not been advanced, and the firm stand of the corporation for stability of prices, both of raw and finished products, has had a most assuring

effect on the trade. The stockholders of the United States Steel Corporation number about 60,000.

**Iron Ore.**—The production of iron ore in the United States in 1901 amounted to 28,887,479 long tons, against 27,553,161 long tons in 1900. Minnesota, which is now the leading iron ore State, registered the largest increase, producing 11,109,537 long tons in 1901, against 9,834,399 tons in 1900, an increase amounting to 1,275,138 long tons.

The total imports in 1901 were 966,950 tons, against 897,831 tons in 1900. Cuba in 1901 supplied 522,723 long tons, against 419,632 long tons in 1900, the principal shippers being the Juragua Iron Co., Ltd., the Spanish-American Iron Co., and the Cuban Steel Ore Co., the latter shipping for its first year of business, 17,651 long tons. The furnaces on Puget Sound, Washington, received some shipments from British Columbia and Alaska, and the balance of the importations came from Spain and Newfoundland. The exports of iron ore for the year 1901 were but 64,703 long tons, against 51,460 long tons for 1900.

While the production of pig iron in the United States showed a very considerable increase over 1900, the consumption of pig iron increased more rapidly, amounting to 16,228,796, as shown by the subjoined table:—

CONSUMPTION OF PIG IRON IN THE UNITED STATES. (IN LONG TONS.)

|                             | 1900.             | 1901.             |                             | 1900.             | 1901.             |
|-----------------------------|-------------------|-------------------|-----------------------------|-------------------|-------------------|

output of steel rails during the year, Pennsylvania produced slightly less than one-half. Adding the 1,730 tons of iron rails produced in 1901 to the total of steel rails by the open-hearth process (2,093 long tons) and the total Bessemer steel rails (2,870,816 long tons), the grand total of steel rails produced during the year amounted to 2,874,639 long tons.

The subjoined table shows the production of rails as compared with that of Bessemer steel ingots, for the past six years:—

| Year.     | Tons Ingots | Tons Rails. | Per Cent. | Year.     | Tons Ingots | Tons Rails. | Per Cent. |
|-----------|-------------|-------------|-----------|-----------|-------------|-------------|-----------|
| 1896..... | 3,919,906   | 1,108,692   | 28.1      | 1899..... | 7,596,354   | 2,240,767   | 29.5      |
| 1897..... | 5,475,315   | 1,614,399   | 29.4      | 1900..... | 6,684,770   | 2,361,921   | 35.3      |
| 1898..... | 6,609,017   | 1,955,437   | 29.6      | 1901..... | 8,713,902   | 2,636,273   | 30.5      |

(a) Not including rails made from purchased blooms or re-rolled rails.

The production of open-hearth steel in 1901, including direct steel castings, was 4,656,309 long tons, against 3,398,135 long tons in 1900, an increase of 1,258,174 tons, or over 37%; the basic process steel amounted to 3,618,993 long tons, and the acid process steel to 1,037,316 long tons. The production of open-hearth steel in 1901 was derived from 90 works in 14 States. Neither Maryland, Kentucky, Michigan, nor Minnesota made open-hearth steel during 1901, although all of them were producers in 1900, and Rhode Island made open-hearth steel during 1901 for the first year of production. The total production of open-hearth steel castings included above amounted to 301,622 long tons during 1901, of which 94,941 tons were made by the basic process and 206,681 tons by the acid process. The production of crucible steel in the United States during 1901 amounted to 98,513 long tons, against 100,562 tons in 1900.

*Tin Plate.*—The production in long tons of finished tin plate (including dipping plants) is given by James M. Swank as follows:—

| Year.     | Tons.   | Year.     | Tons.   | Year.     | Tons.   |
|-----------|---------|-----------|---------|-----------|---------|
| 1893..... | 55,189  | 1896..... | 160,362 | 1899..... | 260,875 |
| 1894..... | 74,930  | 1897..... | 256,598 | 1900..... | 302,665 |
| 1895..... | 113,666 | 1898..... | 326,915 | 1901..... | 399,291 |

*Changes in Iron and Steel Metallurgy.*—The long expected decision of the United States Supreme Court in *Jones* against the Cambria Iron Works, has been rendered in favor of the Jones mixer, the patents of which are now among the assets of the United States Steel Corporation. The decision was sweeping, virtually rendering the use of all mixers of any size subject to the rights of the Jones patents. Interests connected with the Lackawanna Iron & Steel Co. have purchased the controlling interest in the Continuous Metal Refining Co., which owns the Talbot patents. The Talbot process has been in use at the Pencoyd Iron Works, in Pencoyd, Pa., for about two years. In the early part of 1901 a very complete bibliography of "Steel Works Analysis," prepared by Harry Brearley, was published by the *Chemical News*. Experiments for the production of steel by electricity carried on at Gysinge, Sweden, are claimed to be so successful that the present plant, said to produce 25,000 lb. of high-grade steel daily, is to be moved to the Dalalfuen river, where a large water power is to be utilized.

The improvements in pig iron manufacture are exhaustively treated elsewhere in this section by John Birkinbine, under the caption "Modern Improvements in the Manufacture of Pig Iron."

#### THE IRON MARKETS IN 1901.

Although 1901 opened with a rather discouraging outlook for the American iron trade, the conditions improved rapidly in the early months, and to such an extent that the year's business was extremely profitable to the manufacturers. The demand for iron and steel was sufficient to keep the furnaces and mills running at their full capacity, resulting in an output that exceeded all records. The general level of prices was below that of 1900, but the trend was upward from the beginning, and there were no such violent fluctuations to unsettle the market as characterized that year.

*Alabama.*—The records for the year show an increase in shipments of iron and healthy conditions prevailing in the trade. Prospects were doubtful in the first quarter, but the spring months brought a better demand, which continued for the remainder of the year. At the close, the market was firm and strong, with good quotations and plenty of orders. Manufacturers are looking to the future with confidence and some are preparing to increase the output of their plants.

*Chicago, Ill.*—The pig iron consumption in this district increased fully 10% over previous years. Prices were steady; at no time was the variation greater than \$1 per ton. Trade was hampered by the inability of the railway companies to handle the traffic, and the year closed with no improvement in this respect. The outlook for the future is encouraging, although some dealers and manufacturers incline to the belief that a slump in prices will come before the end of 1902. The consumption of pig iron in the Chicago district in 1901 is estimated at 2,250,000 tons.

*Cleveland, Ohio.*—The production of pig iron in this section in 1901 was unprecedented, and there was hardly a time that the demand did not exceed the output. Prices were steady throughout the year. Large sale of material, especially steel, were made on contracts covering the output of the furnaces for a period of six to fifteen months.

**Pittsburg.**—The past year was more satisfactory to the iron and steel interests than 1900 or 1899, despite the big strike of steel workers, which curtailed the production of the United States Steel Corporation by thousands of tons. While prices did not reach as high a point as in the preceding two years, the output of mills and furnaces was much larger. The capacity of many plants was increased and new works were built, but at no time was the production in excess of the demand. The year opened with Bessemer iron considerably depressed in price and small sales were made as low as \$12.25 at Valley furnace. The buying movement was started by the Carnegie Steel Co., which contracted for 150,000 tons of Bessemer pig at \$12.50, and other sales were negotiated, bringing the January total up to 215,000 tons. Bessemer billets remained at the fixed price of \$19.75 per ton until April, when the price was advanced to \$24. There was a strong demand for sheet and tie bars, and the quotations ruled high throughout the first half of the year, sales having been made at \$28 and \$29 per ton. Tank plates sold at \$1.40, but soon were advanced \$2 per ton, and by another \$2 in April. Rails, standard sections, sold for \$26 per ton until April, when the price was raised to \$28, at which figure large contracts were made that practically fixed the prices, not only for the remainder of 1901, but also for 1902. The demand for light rails in the latter part of the year was without parallel, and high prices

were paid for fair deliveries. Sheets, No. 28 gauge, brought 2·95c. in January, advancing to 3·35c. in February, where they remained until July 1, when a reduction to 3c. was made for large lots. Bessemer pig advanced to \$14 in February, with the increasing demand, and during the next two months prices reached \$16@ \$16·25. In July the United States Steel Corporation established a central pig iron purchasing department, through which all iron for the constituent companies is bought. For the remainder of the year prices ranged from \$15·50 to \$16; in December prompt deliveries commanded a premium over these figures, owing to a serious shortage of coke which forced many of the furnaces to bank. Sheet bars in the latter half of the year were strong and sales were made for prompt deliveries as high as \$30 and \$31 per ton. Tank plates from April to December remained at 1·60c., with a good market. The great need of the Pittsburgh district is increased shipping facilities. The freight congestion is becoming worse each year, and until relief is had the proper operation of furnaces and mills will be greatly hampered.

(a) No quotations available as quantities used in Pittsburgh are comparatively insignificant. (b) Cents per pound.

## PRODUCTION OF PIG IRON AND STEEL IN THE WORLD.

The total production of pig iron for the world in 1901 was 40,785,605 metric tons, an increase of 587,011 metric tons over that of 1900, while the production of steel amounted to 31,018,490 metric tons, an increase amounting to 3,040,861 metric tons for the year. A comparison of the relative production of pig iron and steel during the past few years shows that annually greater proportions of pig iron are being converted into steel, due to the demands for structural purposes, as well as to decreases in the cost of manufacture. Large quantities of steel are absorbed for the production of cars and structural steel. The prosperity in iron and steel was greatest in the United States in 1901, the production of both in the United States being more than Germany and Great Britain combined. Germany and the other European countries suffered greatly from depression in the iron and steel trades during the year. The statistical diagram which is given later in this section, shows very clearly the relative position occupied by the products of iron and steel during the past 25 years. Of the world's production of pig iron in 1901, the United States made 39·5%, the United Kingdom 19·3%, and Germany 19·2%, a total of 78·0% of the entire output for the year. The

percentage of the world's production of steel for 1901 was for the United States 44.1%, United Kingdom 16.3%, Germany 20.6%, a total of 81.0% of the world's supply.

*Belgium.*—The total production of pig iron in 1901 was 765,420 metric tons, against 1,145,654 metric tons in 1900, showing a decrease of 380,234 tons. These totals include foundry, forge, and steel pig. The total production of steel in 1901 was 526,670 tons, against 655,199 tons in 1900, a decrease of 128,529 tons. While there was a considerable falling off in the production of various grades of pig iron during 1901, the production of finished iron showed some progress, but this was offset by a decline in the output of steel. The number of furnaces in blast on December 31, 1901, was 26, against 31 for the corresponding date of 1900.

*Canada.*—The production of pig iron during 1901 was 244,976 long tons, against 86,900 long tons in 1900, a very considerable increase during the year. Of the total output of pig iron, 228,893 long tons were coke iron, and 16,083 long tons were charcoal iron. The production of Bessemer pig iron was 29,577 long tons. No spiegel iron nor ferromanganese was produced during the year. The annual consumption of pig iron and steel and their products in Canada is between 800,000 and 820,000 long tons. The exports of iron ore during 1901 amounted to 306,199 short tons. On December 31, 1901, there were 12 completed furnaces and four more in course of construction, with a total aggregate capacity of nearly 1,100,000 long tons. The investment of capital in Sydney, Hamilton, Deseronta, Midland, New Glasgow, Radnor, Drummondville, and Ferona amounts to \$24,500,000 which will be increased to \$35,000,000 with the completion of a new furnace early in 1902. The Lake Superior Power Co., at Sault Ste. Marie, Ont., is building an extensive plant for making pig iron, steel, and steel rails, the latter the first plant of its kind to be erected in Canada. Of the four furnaces which were erected during 1901, by the Dominion Iron & Steel Co., at Sydney, Cape Breton, N. S., three were put into blast during the latter part of the year, and the fourth in January, 1902.

*France.*—The production of pig iron in 1901 was 2,400,240 metric tons, against 2,714,298 metric tons in 1900, a decrease of 314,058 metric tons for the year. The production of all kinds of steel during 1901 amounted to 1,465,071 metric tons (against 1,565,164 tons in 1900), which was distributed as follows: Bessemer steel ingots, 860,425 tons; open-hearth steel ingots, 604,646 tons. There was a decided falling off in all branches of the iron and steel industry during the year.

*Germany.*—The production of pig iron in Germany, including Luxemburg, is reported by the Association of German Iron and Steel Makers in the following table:—

| Description.            | 1899.            |              | 1900.            |              | 1901.            |              | Changes.            |

(a) Estimated.

For the nine years previous to 1901 Germany had enjoyed a gain in both iron and steel production with each succeeding year, but the financial depression of 1901 made it impossible for the home market to absorb even the restricted production of the furnaces, and during the closing months of the year German pig was offered at very low prices on the English market. During 1901, 92·7% of the entire steel output was made by the basic process. The fact that over 80% of the pig iron made during 1901 was converted into steel shows the increase in its use and the decreased use of wrought iron.

The production of steel in Germany, as reported by the Association of German Iron and Steel Makers, is given in the subjoined table:—

|                              | 1899.        |       | 1900.        |       | 1901.        |       |

the German methods of classification in their statistical records are so different from those in general use that correct reports are difficult to ascertain. Spiegel is included with forge iron, and while the total production of steel pig for year is given as 4,916,986 metric tons, the total production of steel shows that more than 80% of the total pig iron production was absorbed in steel making.

The highest proportion of basic pig was made from the minette ores of Luxembourg, while about 75% of the Bessemer pig came from the Rhine district.

**Mexico.**—The Compañía Fundidora de Fierro y Acero de Monterrey was organized in May, 1900, with a capital of \$10,000,000 to operate the iron mines on Cerro del Cuernavaca Mountain, on the line of the Mexican National Railroad, and at Monarcas, on the Mexican International Railroad. Two of the Cerro del Cuernavaca Mountain mines are large enough for present needs, and the ore is being conveyed by two chert tramways carrying about 1,000 tons daily from the mines to the loading terminal of the branch railway, about 5 miles from Golondrina station on the main line of the Mexican National Railroad. The ores of the various mines owned by the company supply magnetite, hematite, or brown hematite, all of good quality, and comprise the only deposits of Bessemer iron known to exist in the Republic. Manganese ores varying from 40 to 55% of metallic manganese and low in phosphorus are readily obtainable in the vicinity, and limestone of an excellent quality is found in enormous quantity close to Monterrey. The Laredo field of 30,000 acres is owned by the company, and it also owns in part the fields at Barroteran, which are suitable for blast furnace coke. The plant at Monterrey comprises one large blast furnace and three 35-ton open-hearth steel furnaces, all equipped with electric charging and carrying machinery. Besides the dry, machine shop, blooming mill, etc. The plant is equipped to manufacture rails, beams and shapes, billets and bars, pig iron and castings, and has a capacity of about 128,000 tons per annum.

**Norway.**—The Dunderland Iron Ore Co., Ltd., capitalized at \$10,000,000, has leased from the Norwegian Government extensive ore beds about 18 miles inland from Mo, on the Røan Fjord, in the North Sea. It is estimated that 100,000 tons of iron ore, bearing 40% iron, are available in one deposit. An iron-ore plant will be erected after plans of Turrettini, the well-known Swiss hydraulic engineer, about midway between the mine and tidewater, where a water-lift 112 ft. high, which will yield from 10,000 to 15,000 H.P., will be utilized in the Edison's electric concentrator process. A railroad will be built from mine to water, and the entire equipment will be from American factories. The iron ore will be crushed, passed through the Edison magnetic separator, and then made into briquettes for the blast furnace.

**Russia.**—The complete figures for the production of iron and steel in Russia are not available at the time of publication, but from the data at hand, it is evident that the production of both commodities for 1901 will be slightly less than for 1900, which is officially reported at 2,895,636 metric tons for pig iron, and 1,830,260 metric tons of steel.

**Spain.**—The production of iron ore and iron and steel products which is annually reported by the *Revista Minera* in advance of the Government report, has not appeared at the time of publication this year. The production of iron ore in 1900 amounted to 8,840,246 metric tons. The exports of iron ore during

1901 were 6,637,613 metric tons, as compared with 7,823,270 metric tons in the previous year, which shows a decrease of 1,185,657 metric tons. The products of iron and steel during 1899 and 1900 are given in the subjoined table:—

|                               | 1899.   | 1900.   |
|-------------------------------|---------|---------|
| Pig iron.....                 | 295,840 | 294,118 |
| Wrought, or puddled iron..... | 66,568  | 63,045  |
| Bessemer steel ingots.....    | 68,300  | 91,586  |
| Open-hearth ingots.....       | 49,350  | 59,048  |
| Finished iron and steel.....  | 173,566 | 212,121 |

The amount in metric tons and the destination of the exports of iron ore from Spain for the past five years are given in the subjoined table:—

| Destination.         | 1897.     | 1898.     | 1899.     | 1900.     | 1901.     |

| Totals.....          | 6,884,588 | 6,558,060 | 8,613,137 | 7,823,270 | 6,637,613 |

(a) Statistics not available at time of publication.

*Sweden.*—(By Richard Akerman.)—The following iron and steel products of Sweden during 1901 were reported direct to THE MINERAL INDUSTRY by the General Director of the Official Mineral Statistics of Sweden. The figures are in metric tons: Iron ore, 2,795,160; pig iron, 528,375; steel blooms produced from pig iron in charcoal hearths, 164,850; Bessemer steel ingots and castings, 77,231; crucible steel ingots and castings, 1,088; open-hearth steel ingots and castings, 190,877; blister steel, 701; bar iron and steel, 152,183; nail and wire rods, band iron and steel, 89,135; otherwise shaped iron and steel in bars, 6,282; plates (sheets not included), 13,856; tube-blocks, hollow blooms, and billets, 14,333. The number of furnaces in blast during the year was 139, the average daily product per furnace being 13.96 metric tons, the average time each furnace was in blast was 272 days. The exports of steel and iron products from Sweden during 1901 are elsewhere reported in metric tons as: Iron ores, 1,761,000; pig iron, 84,600; charcoal blooms, 18,900; steel ingots, 5,900; bar iron and steel, 142,100.

*Switzerland.*—It is reported that electric smelting for iron and steel is to be inaugurated on a large scale during 1902, near Meiringen, in the Bernese Oberland, and that the State has given a concession for the working of an outcrop of hematite which is 7 ft. in thickness for a distance of two miles in length. 60,000 H. P. is to be utilized from a water-power in the vicinity, and the ore will be transported to Innerkirchen, in the valley below, by means of an aerial tramway. Lack of fuel for smelting has heretofore restricted the development of metallurgical industries in Switzerland.

*United Kingdom.*—While the British and American iron and steel trades have heretofore customarily paralleled each other in progress, during 1901 the United States exceeded all previous records in production, while the United Kingdom produced but 7,886,019 metric tons of pig iron, against 9,003,046

ic tons during 1900, a decrease of 1,117,027 metric tons for the year. The uction of steel for 1901 was 5,080,000 metric tons, against 5,130,800 metric for 1900, a decrease of but 50,800 tons, which did not compare with the ase in pig iron production. The home consumption of pig iron and steel ed little change, the decrease in both products being due to increase of s at the close of the year (a total of about 65,000 tons being on hand) and ased exports to Russia and Germany, owing to the financial depression exist- in those countries. During 1901 there was a considerable fall in prices of ron; Scotch pig at the opening sold for at about \$14.50, while at the close e year the price fell to about \$11.50; Cleveland pig fell from \$12 at the ing to \$10.25 at the close of the year; while hematite or Bessemer pig iron ed from \$15.25 to \$13.25 per ton. The prices of finished material decreased dingly. Iron and steel bars decreased in price about \$6 during the year; s about \$5; steel rails and ship plates about \$2.50. During 1901, 55 blast ces suspended operations.

e production of steel in the United Kingdom is detailed in the subjoined :-

| Variety.         | 1898.         | 1899.       | 1900.         | 1901.      |

### MODERN IMPROVEMENTS IN THE MANUFACTURE OF PIG IRON.

BY JOHN BIRKINBINE.

IE rapidly increasing production of pig iron in late years is due to numerous ges in plant construction, equipment and management which have resulted the application of scientific principles and efficient business acumen. Among factors may be mentioned the following:—

The exploitation on a liberal scale of large iron ore deposits which have available immense quantities of ore previously unexpected, the erection cks, construction of vessels and special handling appliances for the trans- tion and delivery of these quantities. Similar developments of coal mines, ruction of coke ovens and the introduction of means for cheaply handling

both the crude material and the finished product have supplemented the efforts to secure supplies of ores.

2. The growth of the steel industry, first in the line of "Bessemer" steel and later in the development of "open hearth" steel has had a most potent influence in furnishing a market for metal and in regulating its quality.

3. The enlarged proportions of blast furnaces, with greater blast pressure and higher blast temperatures have produced not only furnaces of greater size, but have increased very largely the capacity from a given unit. Possibly the extent to which technical investigation has been followed in the operation of the blast furnace and the determination of the characteristics of ore, fuel and flux, has done as much as anything else to achieve these results and surely it is not second to the wonderful perfection of mechanisms which have been introduced in the plants which are now prominent producers.

*Iron Ores.*—In late years three or four prominent iron ore mines in the United States have each produced 1,000,000 tons or more of ore, and the maximum output from a single operation, either in the United States or, as far as known, in any other part of the world, was reached by the Fayal mine, which in 1901 supplied 1,681,000 tons of merchantable ore. Since 1883 from 5 to 15 of the iron ore mines in this country have contributed over 500,000 tons each in a year. Most of the mines reporting these large outputs are in the Lake Superior region, where navigation is suspended for four or five months in the year, and although development work is prosecuted during the winter, it may be considered that these large quantities are won at the rate of from 2,500 to 7,000 tons per working day from the mines mentioned. There are important mines elsewhere, and among those which have supplied 500,000 or more tons per annum are individual mines in Alabama and Pennsylvania. These statements taken in connection with the fact that the bulk of this ore is sent to furnaces from 500 to over 1,000 miles distant and that shipments from the Fayal mine in one month reached 375,814 tons, demonstrate the growth of the iron ore mining industry.

It is, however, not only the facilities for mining large quantities of iron ore cheaply which command attention, but also the means of transporting them from mines to vessels and delivering them into vessels' holds, the equipment, capacity and speed of the vessels themselves and finally the appliances for removing the ore from these vessels and transporting it to furnaces.

The quantity of iron ore mined in the United States in the last decade has increased from 16,000,000 to 29,000,000 long tons by the improvements in mining machinery and mining methods in the use of large cars, heavy locomotives, substantial railroad construction, powerful vessels, and elaborate dock equipment, and by the liberal employment of steam, electricity and compressed air. An important feature also has been in the close application of chemical analyses to the grading of iron ores, whereby an ounce of phosphorus in a long ton of iron ore may place it within or without the Bessemer limit. The Lake Superior region produces about three-quarters of the iron ores won from the mines of the United States.

The Bessemer steel industry increased the demand for iron carrying small amounts of phosphorus, and threatened to interfere with the development of a

few large iron ore deposits in which this element was in greater proportion than was desired or was acceptable as within what is commercially known as the Bessemer limit (a limit which has been practically reduced until in a standard ore but one part of phosphorus to 1,300 or 1,400 parts of iron is allowed). However, with the later growth of the open-hearth steel industry, the demand for ores not within the Bessemer limit has been increased, although a low phosphorus ore is preferred in the majority of cases.

*Fuel.*—The original fuel used in the blast furnaces until 1840, was confined to charcoal, then anthracite and bituminous coals were employed, and in 1855 the quantity of pig iron smelted with anthracite exceeded the quantity made with charcoal, but as the application of coke in place of raw bituminous coal advanced, it passed anthracite in 1875 as a popular blast furnace fuel. At present fully 87% of the blast furnaces for iron in the United States are charged with coke; anthracite ranking next in order, and charcoal last. The output of the charcoal furnaces in 1901 amounted to only 382,441 tons.

Some of the pig iron reported as made with anthracite or charcoal is produced with a mixture of coke and the fuels named.

To supply the demands of the large furnaces, a liberal development of bituminous coal mines and an augmentation in the number of coke ovens has been necessary. The selection of desirable coking coals in which the proportion of sulphur and phosphorus are within the required limits has encouraged the introduction of by-product ovens in which the products of distillation are in part used for heating these ovens, obtaining a large yield from the coal charged and permitting the utilization of coals in which the volatile matter is insufficient to maintain the heat in the ordinary bee-hive oven. It is now proposed to improve still further the coke made in some of these by-product ovens by compressing the coal in advance, thus obtaining a greater yield from each charge and securing a denser product and compensating for the swelling or contraction which is often troublesome in the manipulation of the ovens.

A late departure in the supply of fuel has been by the erection of ovens at the blast furnace, the coal being brought from a distance. This departure is confined to by-product ovens, and it is expected to obtain value either from the by-products, or the use of the excess gas if the coal used is high in volatile matter.

*Blast Furnaces.*—The growth in the dimensions of blast-furnace stacks received a decided impetus within a few years and stacks were constructed higher and of larger bosh and crucible diameters than had heretofore been built except in isolated instances. It is questionable whether further increase in these directions will be generally considered as desirable. There are apparent limitations in the height of the furnace and in the diameter of the crucible which affect the fuel, especially when it is used in connection with a large proportion of finely comminuted iron ore.

The descending column in a large blast furnace subjects the coke (the fuel now generally used) to considerable abrasion, producing in a high furnace with a longer shaft more coke dust than in a low furnace. Furthermore, the method of handling the coke from the cars to the bins, thence to the weigh cars and the skips, and finally through two charging bells, encourages its decrepitation. It is

also claimed that in the long narrow shafts of the higher furnaces, the swelling of the reduced ore affects the blast resistance. The pressure to overcome this resistance as well as that due to the column of stock and that required to permeate the wider hearths, seems to exceed the resisting capacity of many of the cokes, and as a result the decrepitation of the coke is still further increased, and accumulations of this fine material form in the blast furnace above the point where the fuel may be expected to be in active combustion. Owing to obstructed blast, pressures which under normal conditions would not exceed 12 to 15 lb. per sq. in. at the tuyeres are increased to 20 lb. and over with a tendency, under existing conditions, for the furnaces to channel and work irregularly. At the time of writing few of the larger furnaces are producing proportionately more iron or iron on lower fuel consumption than those which a few years ago were considered large. That is, blast furnaces ranging from 20 ft. bosh diameter up to 23 ft., with crucibles 13 to 16 ft. diameter, and heights from 95 to 105 ft., are not as a rule doing better work or materially exceeding in output those of a bosh diameter not over 20 ft., with crucibles not exceeding 12 or 14 ft. in diameter and of a height approximating 90 ft.

A radical development has been made in the means of delivering the raw materials into the furnaces. The general method had been to drop the ore, flux and fuel from cars running on trestles to piles below the tracks, then to shovel or fork the material into charging barrows and to wheel them to a vertical elevator or inclined plane, and there consign them to top fillers, who deposited their contents on to the bell of the furnace. This is being replaced by a series of bins, which form portions of the trestle; chutes from these bins deliver the material into charging scale cars, which in turn shoot the ore, flux or fuel into skip cars, although at some furnaces, the materials are fed direct from the bins to the skip cars. The skip cars travel on inclined planes and are dumped at the top of the furnace into a receiving hopper with bell, which when full deposits its load in the main hopper, the upper bell closing as a seal. Friable material such as coke and such ore as breaks readily is more finely comminuted in the bin system, as described above, than in the older method mentioned, and it is probable that the modifications of the stock-handling appliances will be in the direction of reducing this decrepitation and loss. The use of bins has necessitated a more liberal crushing of ore than has previously prevailed, and it is difficult to discharge lumps of large size through the spouts. This necessity for crushing also produces ore of a more uniform size and undoubtedly facilitates the smelting process.

Good management recognized the disadvantage of dividing a charge which may represent as much as five tons of one kind of ore into as many as 10 barrows, to be pushed by men to the foot of the hoist or incline. By means of bins and of scale and stock cars these charges are now fed in larger units, which results in a material saving of labor and a full supply to the large furnaces. In discussing the handling of ores, fuel and flux are also included.

In constructing furnaces the whole equipment must be designed for the work, and a plant to make 300 tons per day should have its boiler capacity, its blowing engines, its hot-blast stoves, etc., all proportioned for this product. If a fur-

is to produce 500 tons per day, a corresponding increase is demanded in the features of the plant. This increase is not confined to dimensions of the land and of the parts mentioned, but extends to steam pipes, gas and blast sections, and to the apparatus for delivering the stock to and removing the product from the furnace. The maximum pressure under which the volume of gas is to be delivered controls the capacity and strength of the blowing engines and the power of the boiler equipment. Consequently the large furnaces require expenditure of an amount of money greatly in excess of those of more moderate size.

Hot-blast stoves have increased in height and diameter and the simpler forms with liberal openings and substantial partitions have prevailed. Some stoves exceed 100 ft. in height and others are 25 ft. in diameter; the shell is made of heavy steel, and as a rule, four stoves are allotted to each blast furnace, with the object of obtaining a uniform temperature rather than of securing the maximum heat, which may be obtained intermittently from the incandescent refractory lining.

In manipulating the furnaces a steam or air gun for closing notches and the general application of large metal troughs with skimming attachments for delivering iron and cinder into ladles are features common to the more modern plants.

An item of blast-furnace construction which in late years has received attention is the multiplicity of tuyeres, but this branch, like many other innovations in blast-furnace equipment resulting from a change without careful study, has been disastrous in a number of instances. The single open tuyere of the older charcoal furnaces was supplemented by another opposite to the first, and as the furnaces were enlarged and the tuyeres closed, three, four, and sometimes five tuyeres were used. Later the number of tuyeres was increased but up to within the past decade few furnaces exceeded six, or at most, eight tuyeres. The introduction of as many as 20 tuyeres in the hearth of a large blast furnace encouraged managers to follow this example, and there are instances where sixteen tuyeres were used in a relatively small crucible. The craze for a large number of tuyeres, however subsided, and in most of the large furnaces the number has been reduced to ten or twelve, and in some cases to eight tuyeres.

The liberal use of water cooling for the bosh walls and the crucibles has increased the number of bosh plates, and decreased the intervals between these plates so that in some blast furnaces the boshes are practically a series of bronze water-cooled boxes separated by light fire-brick walls, which are held in place by substantial bands.

In removing the gases from the larger furnaces, two down-comers or a bifurcated down-comer connecting on opposite sides of the furnace-top and uniting in a common conduit, lead to large dust catchers, and in several instances these dust catchers are connected with gas washers to collect and reserve for future use the accumulation of fine ore and coke which is carried from the furnace by the outgoing gases. This fine ore is principally the comminuted material which comes from some of the large mines in the Lake Superior region, and the amount

produced is influenced by the growing quantity of concentrated iron ore which is being utilized in the blast furnaces.

Considerable dust also results from the breaking of the coke as above mentioned. To reduce the amount of dust carried over by the flues some late constructions withdraw the gases in several vertical flues extending some distance above the top of the furnace and then connect to a common down flue.

Another specialty of modern blast-furnace construction is the application of water tube boilers in place of the long cylindrical boilers with mud drums and the return flue boilers formerly used at most of the blast furnace plants. The water tube boilers occupy less ground space and produce steam more rapidly, but they do not possess the reserve capacity, as a rule, of the older form. Taking into consideration the foundations, setting and buildings to cover the boilers, the cost of installing is in favor of the water tube type. This is especially true when the higher pressure available is considered. A modern furnace plant is now equipped with from 3,000 to 4,000 H.P. of boilers.

In blowing machinery, aluminum grid valves or positive motion air valves for the blowing cylinders, economical valve motions for steam cylinders, and the application of condensers, or compounding engines so that twin engines can be run as one compound machine, has been noticeable. These engines have been mostly of the vertical type with the blowing cylinder above the steam cylinder, but some large lately installed plants are of the horizontal type. As the requirements of the larger furnaces, both for volume and pressure, exceed those of former practice (the volume in some furnaces reaching 70,000 cu. ft. per minute and the pressure at times approximating 30 lb. per sq. in.), these engines are costly features and require commodious and high engine houses of sufficient rigidity to support traveling cranes so that in case of emergency the parts of the ponderous engine can be quickly handled.

With the increased number of tuyeres and the enlarged diameter of those used and the general application of water cooling appliances about the bosh of the furnace, and about the valves at hot blast stoves, added to the requirements for boilers and for condensing steam, the demand for water for a blast furnace of large size is great, and where casting machines are used an additional quantity is required. At present in the larger plants from 3,000,000 to 4,500,000 gal. per day per furnace is provided.

In handling molten metal and cinder, the prevailing practice is to dispense with the familiar cast house in which iron was cast into pigs, and to discharge the molten metal and the cinder into ladle cars, the former being transported either to mixers at Bessemer plants or to casting sheds where the pig iron is run into ordinary molds or to casting machines in which moving molds on strands of chains or rotating about a central pivot are filled and automatically emptied. Comparatively little of the raw materials received or of the metal produced at a modern blast furnace is handled by manual labor, the force about the furnace being confined practically to those who direct the discharge of the raw materials from the railroad cars into the bins and from the bins into the scale cars, etc., or to those who control the flow of metal or cinder from the tapping holes to the ladle cars. There is necessarily a considerable amount of labor required

about a blast furnace to attend to the engines and boilers, tuyeres, hot-blast stoves, etc., and in the stock yard also there are men to receive stock and clean up, while others are necessary to look after the minor details of furnace operation, but the tendency in late years has been to eliminate manual labor in the operation of the blast furnace.

The casting machine has made a radical change in the form of pig used, a slab rather than a bar representing the shape that is cast on most machines. These machines have also done away with the sand allowance (as did also the stationary chills used in cast houses) and has practically abolished the pig iron ton of 2,268 pounds. The future improvements in casting machines seem to be in reducing the number of wearing parts and possibly of producing pigs in the form of a small ingot.

The equipment of ladles to handle the liquid metal and cinder as it runs from the furnace, to convey the former to the mixer, converter or casting machine, and the latter to dump piles, together with the locomotives to handle the ladles and the extensive track systems necessary to have ample ladle capacity always available at the furnace or to accommodate cars loaded with ore, fuel, flux, flue-dust, etc., all help to swell the total outlay for a single plant until those lately constructed have cost from \$750,000 to \$1,000,000 each. This fact, coupled with the desirability of having several blast furnaces in one plant connected as a means of supply for a steel works, and the necessity of having control of ore and fuel supplies for an industry which makes such heavy demands, has taken the blast furnace largely out of individual or partnership control. The majority of those lately constructed belong to companies which, in a number of instances, have consolidated to form aggregations of capital operating a number of blast furnaces that demand enormous supplies of raw materials; hence plants of this type have become important features in the business enterprise of the country.

While this paper is not intended to be statistical, the following figures, indicating the active furnaces and their product, will emphasize the development of the pig iron industry in the United States during the past 25 years:—

| Year.     | Furnaces in Blast<br>at Close of Year. | Total Number<br>of Furnaces. | Production.<br>Gross Tons. |
|-----------|----------------------------------------|------------------------------|----------------------------|
| 1875..... | 298                                    | 713                          | 2,023,733                  |
| 1880..... | 446                                    | 701                          | 3,835,191                  |
| 1885..... | 276                                    | 591                          | 4,044,526                  |
| 1890..... | 311                                    | 563                          | 9,203,708                  |
| 1895..... | 242                                    | 463                          | 9,446,305                  |
| 1900..... | 233                                    | 406                          | 13,789,242                 |
| 1901..... | 266                                    | 406                          | 15,878,534                 |

Assuming that the mean of the total number of furnaces in blast at the commencement and close of each year above quoted was a fair average of those operated throughout the year and that these were producing 300 days per annum, the approximate average tonnage of pig iron per furnace per day is: for 1875, 21 tons; for 1880, 31 tons; for 1885, 53 tons; for 1890, 94 tons; for 1895, 147 tons; for 1900, 176 tons; and for 1901, 213 tons.

Of the total pig iron production for 1901, 9,596,793 gross tons consisted of Bessemer iron and 1,448,850 of basic pig iron.

The blast-furnace manager must keep each of his large furnaces supplied with

1,500 to 2,000 tons of raw material per day, and must arrange a mixture of the ores available in order to secure a metal of the desired quality; the composition of the ores, the fuel and the flux must be carefully analyzed and watched to produce at each cast more than 100 tons of metal in which the phosphorus, sulphur, carbon and silicon is within very narrow limits.

A liberal supply of water and of gas for boilers and also of gas for hot-blast stoves must be maintained. The operation of the blowing and the pumping machinery as well as that of the electric plant for lighting and power is also under constant surveillance; no break should occur day or night, week-day or Sunday.

Under the conditions of modern blast furnace operation it is not remarkable that the changes in the personnel of management are numerous, for the physical and mental strain is severe and continuous. A manager is judged by his results, he shares in the responsibility of imperfect design and suffers from the delivery of undesirable material, which increases his anxiety and trouble. When the chemical and physical limitations under which the modern blast furnace is operated are taken into account, in connection with the large product demanded, a product whose deficiencies are only recognized in subsequent operations in the converter or mill, it is evident that the position of a blast-furnace manager is not a sinecure.

Independent of the increased size of the blast furnace, there has been an increase in output per furnace, and although the production of the United States in 1901 has never been exceeded, it was obtained from fewer furnaces than were in operation two decades ago when but 1,706,793 gross tons were produced. This result has been brought about by the perfection of the blowing machinery, the use of well constructed hot-blast stoves with the connections (gas or steam) kept airtight and of such proportions as to stand the severe strain placed upon them; but primarily to a more thorough knowledge of the reactions which take place in the blast furnace.

As a result, the large output has been accomplished in many instances by marvelously low fuel consumption. Records have been made which show that in producing hundreds of thousands of tons of pig iron per annum, a consumption of less than 1,800 lb. of coke per ton of metal has resulted. While this economy in operation has been pronounced, the life of the blast furnace campaigns has been extended by the use of water-cooling appliances and improved details of construction. At least three of the blast furnaces in the United States have made continuous campaigns wherein over 1,000,000 tons of pig iron were obtained from each furnace, the campaigns lasting approximately eight years.

Such results would seem to suggest that the criticism upon American blast-furnace practice, based upon the rapidity with which the furnaces are driven being prejudicial to the life of the plant, has not been verified, for large products have been obtained continuously and low fuel consumption secured. It is not an unusual circumstance to find blast furnaces averaging about 500 tons of pig iron daily and in individual instances as much as 800 tons per day has been credited to a furnace as a "spurt." Such a "spurt" represents as the daily output of a single furnace a quantity of metal as great as one of the cold blast charcoal furnaces, which was the prevailing type prior to 1850, would have produced in a whole year.

## LEAD.

THE aggregate production of all varieties of lead in the United States during 1901 showed an increase over the production in 1900 exceeding by 3,015 tons the record figures of 1900. The grand total of soft, desilverized and antimonial leads produced from both domestic and imported ores and refined from imported base bullion in 1901 amounted to 392,344 short tons, as compared with 379,248 short tons in 1900. The totals of desilverized, soft and antimonial leads in short tons, derived from domestic ores in 1901 and 1900 were respectively as follows: Desilverized, 211,368, 221,278; soft, 57,898, 47,932; antimonial leads, 10,656 (includes production from foreign sources), 9,906 (includes 3,200 tons from foreign sources), total domestic leads, 279,922, 279,107.

### PRODUCTION AND CONSUMPTION OF LEAD IN THE UNITED STATES. (IN SHORT TONS.)

| Year.    | Stock of Refined, Jan. 1. (a) | Produced from United States Ores. |        |                 |         | Imported in Ores and Bullion. | Total Supply. | Consumed. | Exported in all Forms. | Stock of Refined, Dec. 31. (a) |
|----------|-------------------------------|-----------------------------------|--------|-----------------|---------|-------------------------------|---------------|-----------|------------------------|--------------------------------|
|          |                               | Desilverized.                     | Soft.  | Antimonial. (b) | Totals. |                               |               |           |                        |                                |
| 1897.... | 13,094                        | 144,649                           | 45,710 | 7,369           | 197,718 | 92,117                        | 302,869       | 211,345   | 60,853                 | 31,161                         |
| 1898.... | 31,161                        | 169,384                           | 50,495 | 8,645           | 238,475 | 89,309                        | 343,845       | 246,989   | 78,108                 | 23,698                         |
| 1899.... | 23,698                        | 171,425                           | 40,808 | 7,877           | 217,085 | 75,423                        | 317,196       | 215,632   | 74,944                 | 26,590                         |
| 1900.... | 26,590                        | 221,278                           | 47,932 | 9,906           | 279,107 | 103,341                       | 414,769       | 241,440   | 100,888                | 66,640                         |
| 1901.... | 66,640                        | 211,368                           | 57,898 | 10,656          | 279,922 | 112,422                       | 457,984       | 307,151   | 97,100                 | 53,733                         |

(a) Includes lead in bond, which amounted to 16,618 tons at the end of 1901, 21,190 tons at the end of 1900, 11,389 tons at the end of 1899, 7,345 tons at the end of 1898, and 6,694 tons at the end of 1897. (b) The entire production of antimonial lead is entered as of domestic production, although part of it is of foreign origin; it is, however, impossible to separate this in the statistics; owing to this inability the division of the American production between antimonial and desilverized is not quite accurate, though the error is not important.

The decrease of 10,025 short tons in the production of desilverized lead during 1901 was the first retrograde movement in the progress of the branch of the metal industry since 1895 and may be attributed to the overproduction in 1900, a year in which the stock carried over was very large, compared with the stocks in previous years. The decrease in the production of desilverized lead, however, was practically offset by the increase in the production of soft lead, which was 9,975 short tons and, including the increase in the production of antimonial or hard lead (a minor proportion of which is of foreign origin) gives a total production of desilverized lead and soft lead from domestic sources and

antimonial lead mainly from domestic sources amounting to 279,922 short tons in 1901, as compared with 279,107 short tons for the same products in 1900. Aggregates which are practically identical.

*Colorado.*—The production of lead in Colorado during 1901 was 74,056 short tons, valued at \$6,419,131, against 82,137 short tons, valued at \$7,770,196 in 1900. The production by principal counties for the two years, as reported by the Hon. Harry A. Lee, is given in the subjoined table:—

| County.          | 1900.       |           | 1901.       |           | County.       | 1900.       |             | 1901.       |             |
|------------------|-------------|-----------|-------------|-----------|---------------|-------------|-------------|-------------|-------------|
|                  | Short Tons. | Value.    | Short Tons. | Value.    |               | Short Tons. | Value.      | Short Tons. | Value.      |

The quantity of ore mined in the Leadville district during 1901 amounted to about 850,000 long tons, valued at approximately \$10,000,000, of which 35,000 tons were zinc ores, 70,000 tons manganese-iron ores, and the remainder lead and copper smelting ores. The quantity of sulphide ores produced could easily be increased to 1,000 tons per day could the smelters handle it. The sulphide bodies on the silver-lead belt have been opened principally through the A. M. W. Small Hope and Greenback combinations, while on the gold belt the Resurrection and New Monarch are the principal miners. The Diamond, Sedalia, Forest City and Fortune are also sinking to open the same shoot.

The zinc situation is very bright, it having been clearly proved that zinciferous ores can be profitably handled and the new smelter at Pueblo will give a market for 600 tons a day. The extension of the railroads to all important mines; the diminishing of the water in the downtown mines; the extension of the mineralized area; the forming of combinations to develop territory now lying idle; and the increased investment of Eastern capital, all contribute to the promising outlook for 1902.

With regard to the lead smelting situation, early in 1901 smelting charges were reduced on tailings and all ores containing a low percentage in arsenic and zinc, in Gilpin County, Colo. The cut in prices was initiated by the Kansas City Works, and effected a reduction from \$3.50 to \$2 per ton on tailings and ores on a 10% silica basis. In July, 1901, the smelting plants in operation in the Leadville district, Lake County, Colo., were the Arkansas Valley plant, handling 1,000 tons per day, and the Boston Copper Smelting Co. The remainder of the local output was smelted in Pueblo and Denver. Later in the year arrangements were being made for an increase in the roasting capacity of the Arkansas Valley plant to enable it to handle 3,000 tons more per month of the low-grade sulphide ores. At Salida, 60 miles from Leadville, the erection of the Ohio & Colorado Smelting Co.'s independent plant was begun. The plant will have a capacity of 1,200 tons of ore per day, of which 300 tons will be supplied by the New Monarch Gold Mining Co., owned by the same interests, and the balance will be secured by purchase from other Leadville mines.

**Idaho.**—The production of lead in the Cœur d'Alène district in 1901 was 8,953 short tons, as compared with 81,535 tons in 1900. The output of silver in 1901 was 3,349,533 oz., as compared with 4,755,877 oz. in 1900. The statistics of silver and lead production in this State are based on direct returns from the mines, with an allowance of 6% for loss of lead in smelting and 2% for loss of silver. There are five important producers in the Cœur d'Alène district who mechanically concentrate the low-grade ore to a product averaging about 50% Pb and 30 oz. silver per ton. The chief producers during 1901 were: The Bunker Hill & Sullivan Mining & Concentrating Co., Cœur d'Alène Development Co., Larson & Greenough, Empire State-Idaho Mining & Developing Co., Frisco Consolidated Mining Co., Ltd., The Mammoth Mining Co., and the Standard & Hecla Mining Co. Considerable interest has been manifested in the Thunder Mountain district, which occupies about 600 square miles in the southeastern section of Idaho. The inaccessibility of the region, which can only be reached by trail, precludes the rapid development of the district even though the mines justify it. A 10-stamp mill began operations at the Dewey mine early in 1902 with promising results; the ores are low-grade breccia, with occasional streaks carrying high values but no well defined lodes, hence it is probable that considerable litigation over apex rights will result. The main body of the gold-bearing material is a rhyolite porphyry, breccia and tuff with fine gold disseminated throughout the mass; the thickness of the bed is estimated to vary from 60 to 600 ft. Specimen ore occurs as dendritic incrustations, which is apparently the result of secondary enrichment from circulating mineral solutions. A small smelting plant is being constructed by the Boston & Seven Devils Co., at Weiser, to treat the ores from the Peacock, Helena and Decorah mines, but will not be in full operation until the completion of the branch line of the Oregon Railroad & Navigation Co., from Weiser to the mines. The White Knob Copper Co. is erecting a smelting plant at Mackay, Custer county, which comprises two 300-ton blast furnaces. A 12-mile electric railway connects the smelter with the mines. The ores, so far as the mine development has been extended, consist of carbonates and oxides and are stated to contain an average of 4% Cu and \$3 gold and silver per ton.

**Iowa.**—(By S. W. Beyer.)—The falling off in the demand for zinc has not materially affected the demand for lead, and most of the energy and capital formerly occupied in the development of zinc properties is now devoted to the opening of lead properties. Prospecting has been vigorously prosecuted during the past year, and several rich mineral bodies have been discovered. The demand held firm and the price steady throughout the year and those employed in the production of lead ore were able to secure good returns for their labor and capital. Practically all the ore produced was galena, and all of it was sold to the local smelter, owned and operated by William G. Watters, of Dubuque. The ore melted during the year amounted to 1,500,000 lb., purchased at an average price \$23 per 1,000 lb. and cleaning up an average of 72% lead. The production of lead in Iowa during 1901 amounted to 600,000 lb., valued at \$13,800. The lead smelted by William G. Watters was contributed by the following States: Iowa, 600,000 lb. (\$13,800); Illinois, 700,000 lb. (\$16,100); and Wisconsin, 0,000 lb. (\$4,600). Total, 1,500,000 lb., \$24,500.

*Missouri.*—The mining district of southeastern Missouri embracing St. Francois, Madison and Washington counties, experienced a prosperous year, and the output showed a substantial gain over previous records. Some valuable discoveries of new ore bodies within the limits of the productive area were made, and in one instance ore was found in outlying territory near Irondale. There was a large amount of improvement work done in extending the mining and milling facilities of the companies operating in the district, which placed them in position to increase their output during the coming year. The Federal Lead Co., now consolidated with the Guggenheim Exploration Co., erected a mill of 500 tons' daily capacity and began the construction of a large smelter at Alton, Ill., where the smelting operations of the company will be carried out in the future. The St. Joe Co. increased the capacity of its mill by 40 per cent., and opened two new shafts, while the subsidiary Doe Run Co. also extended its operations. The National, Desloge and Central mines made important additions to their plants. It is probable that the new deposit found at Irondale will begin producing during the present year; the Irondale Lead Co. has completed one shaft on the property, and the mill and smelter will be ready for operations before the middle of 1902. The Catherine Lead Co. became a producer for the first time last year. In the Joplin district the output of lead ore in 1901 was about 35,000 short tons. The average monthly prices per 1,000 lb. ore were as follows: January, \$23; February, \$22.50; March, \$23.12; April, \$23; May, \$22.87; June, \$23.25; July, \$23.62; August, \$23.50; September, \$23.512; October, \$23.06; November, \$23.25; December, \$23.25. The galena concentrate from the ores of southeastern Missouri frequently contains copper, which is not removed by the process of refining ordinarily practiced in the local smelting works, and causes some of the lead to become "chemically hard." At one works the crude lead contains about 0.2% Cu, which is subsequently reduced by refining to 0.02% Cu, the eliminated copper being gradually accumulated in a matte. An analysis of one carload of ore showed PbO 62.1%, Cu 0.61%, Fe 3.33%, CaO 5.85%, MgO 3.08%, SiO<sub>2</sub> 1.39% and Ag 1.3 oz. per ton. The iron and copper exist in the ore as pyrite and chalcopyrite, and the lime, magnesia and silica represent the gangue of the ore.

*Montana.*—In March, 1901, the lead smelting plant of the American Smelting & Refining Co., at Smelter, near Great Falls, was shut down for an indefinite period. In April, operations at the company's plant at East Helena were suspended on account of labor troubles, but in June the work was resumed and continued throughout the year. The plant has been increased by the addition of a new furnace which, with the four already constructed, enables the company to smelt 850 tons of charge or 625 tons of ore per day. Three large bag houses have been built for the collection of flue-dust, also a large horizontal steel flue extending three-fourths of the way around the plant to conduct the fumes from the furnaces to the bag houses.

*Texas.*—The smelting plant of the American Smelting & Refining Co. at El Paso was almost completely destroyed by fire in July, 1901. An enlarged modern plant has been constructed on the ruins of the old one, and new furnaces were blown in April 15, 1902. The plant is now comprised of seven 200-ton lead

furnaces and three 250-ton copper furnaces, each set having its independent flue system and stack. The furnaces are charged mechanically by 6-ton cars operated by means of a street railroad motor and controller with third-rail system. The cars collect the charge at the ore beds, limerock and coke storage, and are run on to 15-ton hydraulic elevators. They are then elevated 38 ft. to the top of the furnaces, traveling over them to the charging doors, through which the loads are dumped directly into the furnaces. By this system two men handle about 1,000 tons per day. A similar system is used for charging the copper furnaces. The power plant is in duplicate, and consists of seven boilers, of a total of 1,250 H.P. and four blowers of a capacity of 30,000 cu. ft. of air per minute; the latter are direct connected to three tandem compound condensing Corliss engines. No belts are used in this plant except for driving a small blower of 10,000 cu. ft. capacity, which acts as a regulator. The central electric plant in the power house consists of two direct-connected, direct-current generators, mounted on the shafts of two cross-compound condensing Nordberg Corliss engines. The current from these generators is transmitted throughout the plant, operating sampling works, briquetting machinery, pumps, hoists, motor, cars, etc., displacing all of the small steam engines and steam pumps used in the old plant. The power plant is provided with two systems for condensing, one being a large Wheeler surface condenser, the other a Worthington central-elevated jet condenser, the idea being to use the surface condenser during a short period of the year when the water is so bad that it cannot be used in the boilers. During the balance of the year the jet condenser is in service and the surface condenser can be cleaned. The condensed steam from the surface condenser, with the necessary additional water goes back directly to the boilers when the surface condenser is in use. The power house is absolutely fireproof throughout, being of steel and brick with iron and cement floors and is provided with a traveling crane. The main conductors from the generators pass out through a tunnel into a brick and steel lightning arrester house, from which point the various distributing lines go to different parts of the plant. An interesting feature of the new work is the substitution of crude oil from Beaumont as fuel for the generation of power and for the roasting of ores in place of wood, coal or coke.

*Utah.*—The importance of Salt Lake City as a smelting center has been increased greatly, and by the end of 1902 there will be four comparatively new works in operation. These are the 500-ton Highland Boy smelter, the 400-ton Bingham plant, the new 1,000-ton (estimated) plant of the American Smelting & Refining Co., and the 850-ton plant of the United States Mining Co. The two latter will probably be in operation late in the year. Of the older plants which were taken over by the American Smelting & Refining Co., the Germania is the only one which continues in operation; the Mingo is dismantled and the Hanauer completely demolished. The new plant of the American Smelting & Refining Co., at Murray, Utah, is under construction and will doubtless be in operation before the end of 1902. The new works are situated close to the old Germania plant, and, while thoroughly modern, there has been no radical de-

parture in methods, the novelties being in details rather than in the general scheme.

The roasting department comprises a crushing mill and 2 furnace houses, one equipped with Brueckner furnaces and the other with hand-raked reverberatories. The ore is trammed over the roasting furnaces and charged through hoppers. The fire-boxes are arranged with step-grates and closed ash-pits, being fed through hoppers at the end of the furnace. The roasted ore is dropped into cars, which run on a sunken tramway passing under the furnaces and is carried to an incline up which the cars are drawn and afterward dumped into brick bins. From the latter it is spouted into standard gauge railway cars and taken to the smelting department. The roasted ore from the Brueckner furnaces is handled in a similar manner.

The blast furnace department comprises 8 furnaces, each 48×160 in. at the tuyeres, having 10 tuyeres per side, a tuyere passing through the middle of each cast-iron jacket 16 in. wide, and 6 ft. long, which is rather extraordinary. The furnaces are arranged for mechanical charging. The furnace house is constructed entirely of steel and the matte is tapped from the settling boxes and runs into pots on the ground level. The slag overflowing into single-bowl, Nesmith pots, handled by small locomotives. The foul slag is returned by a continuous pan-conveyor to a brick-lined cylindrical steel tank behind the furnace house, whence it is drawn off through chutes as required for recharging.

The charges are made up on the ground level, immediately behind the furnace house. The ore and fluxes are brought in on trestles, whence the ore is unloaded into the beds and the fluxes into elevated bins. These are all in the open, there being only two small sheds where the charges are made up and dumped into the cars which go to the furnaces. There are two inclines to the latter. At the top of the inclines the cars are landed on a transferring carriage by which they can be moved to any furnace of the series.

The dust flue extending behind the furnace house is arranged to discharge into cars on a tramway in a cut below the ground level. This flue, which is of brick, connects with the main flues leading to the chimney. The main flues are built of concrete, laid on a steel frame in the usual manner and are very large. For a certain distance they are installed in triplicate; then they make a turn approximately at right angles and two flues continue to the chimney. At the proper points there are huge dampers of steel plate, pivoted vertically, for the purpose of cutting out such section of flue as it may be desired to clean. Each flue has openings, ordinarily closed by steel doors, which give access to the interior. The flues are simple tunnels, without drift-walls or any other interruption than the arched passages which extend transversely through them at certain places. The chimney is of brick, circular in section, 20 ft. in diameter and 225 ft. high.

The boiler house is equipped with 8 internally fired corrugated fire-box boilers, arranged in two rows, face to face. Between the rows is an overhead coal bin, from which the coal is drawn directly to the hoppers of the American stokers, with which the boilers are provided. Adjoining the boiler house is the engine house, containing two cross-compound, horizontal Allis-Chalmers (Dickson) blowing engines for the blast furnaces, and two direct-connected electrical generating

for the development of the power required in various parts of the works. A traveling crane, built by the Whiting Foundry Equipment Co., spans the engine house.

A noteworthy feature of the new plant is the concrete paving, laid on a bed of broken slag, which is used liberally about the ore yard and in other places where tramming is to be done, including the floors of the roasting furnace houses. The whole plant is well laid out with service tramways and standard gauge spur tracks and the design has been obviously to save manual labor as much as possible.

*Philippine Islands.*—G. F. Becker has reported the partial development of a lead mine near the town of Cebú, on Cebú Island, and a deposit of ore at Marrijos, Marnidugue Island, showed a value of 96 g. silver, 6 g. gold, and 5.5 kg. lead per metric ton.

#### PRODUCTION OF LEAD IN FOREIGN COUNTRIES.

*Algeria.*—The Ain Kechera lead and silver mines are being developed, and the concessions asked for by the owners will probably be granted by the Government, as the official engineer has reported favorably. The ore from the mines will be shipped from Callo.

*Australia.*—The Broken Hill Proprietary Co., during the six months ending May 31, 1901, treated 133,862 tons of ore and concentrates for a yield of 26,361 tons lead, 302 tons antimonial lead, 3,240,756 oz. silver, and 1,342 oz. gold. The average results per ton were 19.69% lead, 24.21 oz. silver, and 0.01 oz. gold. As regards output, the operations were very successful, but there was a shrinkage in profit owing to the lower prices ruling in the market for lead and to the increased costs of smelting. Work was begun in January to connect the smelting works with certain iron ore leases in South Australia from which the company intends to derive its supply of flux; the cost of the iron ore consumed in the furnaces has heretofore been an important item in the treatment charges. Extensive development work was carried out in the mine, particularly in lowering the main shafts and opening levels, which added materially to the ore reserves. Experiments with magnetic concentrators were continued; one machine was installed which gave good results, but it is not intended to erect a plant until exhaustive trials have been made. The coke ovens at Bellambi were put in operation and the first trials were very satisfactory. During the semester ending November 30, 1901, the gross profit was £669,316, and the net profit, after deducting general expenses and depreciation, was £43,319. The dividends paid were £48,000, showing a deficit of £4,681. The surplus brought forward was £548,076; leaving a balance of £543,395 to the current half-year.

The total extraction of ore for the half-year was: From open-cut, 63,533 tons; from underground, 242,095; total, 305,628 tons.

The chloridizing and leaching plants were kept running for 4.5 months only, when they were closed down, as the ore immediately available from the open-cuts is not of a suitable nature for this process. The two concentrating plants continued to do good work. The slimes from the mill, which are difficult to deal with at the smelting works, are now being sintered at Broken Hill.

Smelting operations at Port Pirie continued without interruption. The ton-

age of ore, concentrates, etc., smelted amounted to 105,255 tons, with an average yield of: Lead, 18·6%; silver, 17·92 oz. per ton. The refinery treated 18,984

THE WORLD'S PRODUCTION OF LEAD  
IN METRIC TONS

tons of silver-lead bullion, producing: Silver (fine), 2,296,755 oz.; gold, 7,531 o soft lead, 18,225 tons; antimonial lead, 258 tons.

In addition to the ore smelted at Port Pirie, a quantity of concentrates was s

(a) The statistics for Austria, Belgium, Canada, France, Germany, Hungary, Italy, Japan, Russia, Spain and Sweden are from the official reports of the respective governments except where otherwise noted. Those for Greece are based on the authorities given under the general table of mineral production of Greece in a subsequent part of this volume. Those for the United States are from data collected by THE MINERAL INDUSTRY. Those for the United Kingdom as specified in note b.

(b) The production of lead in the United Kingdom is given in two columns. One gives the amount of lead derived from domestic ores, the yield of which is calculated at 95% as reported in the official British blue books. The other column gives the production of lead in the United Kingdom from foreign ores smelted there. These figures, which are not reported in the official blue books, are obtained by deducting the production of British lead from the total output of the lead smelters of the United Kingdom as stated in the *Statistische Zusammenstellungen über Blei, Kupfer, Zink und Zinn* of the Metallurgische Gesellschaft, Frankfurt-on-the-Main.

(c) From the *Statistische Zusammenstellungen* of the Metallurgische Gesellschaft, Frankfurt-on-the-Main. These figures comprise only the lead exported to Europe and America. The actual production of lead in New South Wales is much larger than shown here, especially in late years, during which there have been large exports to China, but it is impossible to obtain statistics as to what it really amounts to. (d) Estimated.

(i) Production from statistics of the Metallurgische Gesellschaft, Frankfurt-on-the-Main. Imports and exports from Board of Trade returns.

(j) The statistics of production are those collected by THE MINERAL INDUSTRY; those of imports and exports are from the reports of the Bureau of Statistics, Washington.

(k) Not stated.

for export, bringing the output of finished products up to 29,944 tons lead and 2,835,954 oz. silver.

The Broken Hill Proprietary Block 10 Co. in the six months ending September 30, 1901, treated 81,852 tons crude ore, producing 13,676 tons concentrates, with a total content of 464,826 oz. silver and 8,816 tons lead. The net profit on the half-year's operations compared with the preceding semester showed a marked decline.

The declared net values of the exports during 1901 was as follows: Silver, silver-lead, and ores, £1,854,463; lead (pig, etc.), £100,501; zinc (concentrates), £4,057. The bulk of the output was contributed by the Broken Hill mines, and the fall in the prices of silver and lead during 1901 practically crippled the industry and caused the closing down of all but three of the principal mines.

The Smelting Co., of Australia, with the plant at Dapto was reorganized early in 1902, and, while the properties have not yet been transferred, negotiations are in progress for ore supplies and for a reduction of railway rates.

*Canada.*—The production of lead in Canada during 1901 was 25,378 short tons, as compared with 31,679 short tons in 1900. The decrease of output is attributable to low prices for the ores during the year and to difficulties encountered in marketing the ores profitably with the smelters in the United States.

*British Columbia.*—(By W. M. Brewer.)—The silver-lead ores of British Columbia are confined apparently to the southeastern portion of the Province in the Slocan, Trout Lake, Windermere, Kaslo, Lardeau and Fort Steele mining divisions. Besides these occurrences there have been reported discoveries of silver-lead ores near Cowicahn Lake and the Gordon river on Vancouver Island. The progress in mining in the silver-lead districts has not been satisfactory for the past two or three years, owing to labor troubles and the decline of the market in the United States for British Columbia ores. But since the Dominion Government has offered a bonus for refined lead, and the Canadian Smelting Co. at Trail has taken the matter up seriously and commenced the installment of a plant, it is expected that the industry will progress much more satisfactorily in the future than in the past. The Trout Lake and Slocan ores, as well as some of those in the Windermere district, generally carry quite high silver values in addition to the lead. Among the most important of the silver-lead mines are the St. Eugene and North Star mines in the Fort Steele mining division; these are considered among the most extensive bodies of concentrating ores on the North American continent. The dividends paid by the Payne Reco, Slocan Star, Last Chance, Ruth, North Star, Bo'sun, Goodenough, Rambler, Cariboo and other silver-lead mines in British Columbia demonstrate that this class of mining has been profitable and satisfactory. The report of the reorganized Hall Mining & Smelting Co., British Columbia, for the fiscal year ending June 30, 1901, shows a capitalization of £325,000 in £1 shares, of which £275,000 had been paid in; also £24,560 6% debentures. The net profit for mining and smelting amounted to but £1,011. The two furnaces treated 21,657 short tons of purchased lead ores during the year.

*Chile.*—(By W. T. Mathewson.)—The Playa Blanca plant, owned by M. Guggenheim's Sons, of New York, was in operation during the greater part of the year. The smelting works consist of a blast furnace and cupellation department

of nine small furnaces. The ore was derived from the Pulacayo mine of the Huanchaca Co., of Bolivia, the base bullion being shipped to Perth Amboy, N. J. During the first months of its operation the plant was worked at a profit, but later owing to a decrease in the lead contents of the ore other sources of ore supply had to be sought. Lead slags were imported from Oruro, Bolivia, and concentrates from Australia and British Columbia. The importation of such ores, however, was found too expensive, and during a part of 1901 the silver ore was matted with the local copper ores, which contain about one-third of the copper in the form of atacamite. These ores prove undesirable for smelting on account of the volatile copper compounds which carried off large quantities of silver, as well as copper, in furnace gases. For this reason the company decided to close down the plant, which was done in December, 1901. Since that time the ore has been shipped to the company's works in the United States. The output of the Playa Blanca smelting works during its operation by M. Guggenheim's Sons was 7,800 tons of copper matte assaying 50% copper and 390 oz. silver per ton.

*Germany.*—The production of pig lead in Germany during 1901 amounted to 123,098 metric tons, as compared with 121,513 metric tons in 1900; the production of litharge during 1901 was 4,101 metric tons, an increase of 1,013 over the production of 3,088 metric tons in 1900.

*Greece.*—The lead mines of Greece were actively operated in the early part of 1901, but later, due to the decline in the price of lead, many of the mines were forced to shut down. None of the Laurium companies has realized good profits, and the Laurium Lead Works Co. declared no dividend for the closing six months of the year. The smelters treated 340,000 tons of mixed ores and produced 17,694 tons of pig lead which averaged 75 oz. silver per ton. English gas engines are being installed to operate the blast engines, which is calculated to reduce materially the fuel cost of smelting.

*Mexico.*—The production of base bullion in Mexico during 1901 was 79,497 metric tons, as compared with 74,944 metric tons in 1900. The principal sources of lead ore supply are the Sierra Mojada mines in Coahuila, the Santa Eulalia mines in Chihuahua, the Mapini mines in Durango, and those in the vicinity of Monterey, Nueva Leon. Since 1896, in addition to the consumption of lead ores by the smelters in Mexico, at least 150,000 tons of ore have been shipped annually to the El Paso, Texas, smelter. This large quantity of exported ore has been derived from the Sierra Mojada and the Santa Eulalia mines, mainly the former. The ores assay from 10 to 20% Pb and from 12 to 15 oz. silver per ton. The mines and the smelting plants in Mexico are well described by Joseph Struthers in the paper "Mining and Metallurgical Industries of Mexico," published in the *Engineering and Mining Journal*, October 26, 1901. The visit of the American Institute of Mining Engineers during November, 1901, which extended through the more important mining regions of the Republic, will doubtless have a very beneficial effect on the future development of the mineral industries of the country.

*Spain.*—The lead mines in the Linares district supply nearly 40% of the total production of Spain. The principal mines, with the depth of the deepest shaft, are as follows: the Spanish State mine, Arrayanes (350 m.), and those

operated by Taylor & Co. comprising Pozo Ancho (450 m.), Los Cumientos (440 m.), Los Salidos (450 m.), La Fortuna and Alamillos, La Tortilla, San Miguel (525 m.), and Matta Cabra (475 m.). The mining operations are carried on in a primitive manner, small wooden propped head gear and hand hoists being common. The ore is hand picked, the smaller sizes worked on jigs without previous classification, the fines pass to fine jigs and ultimately to Cornish buddles, all operated by hand power. Mr. E. Mackay-Heriot estimates the cost of hand dressing 1 cu. yd. of ore at 4.94 pesetas. The wages for the miners when sinking shafts are 4 pesetas per day, and when driving levels 3.5 pesetas; surface men receive 2.5 pesetas, boys 1.25 pesetas, smiths and carpenters 4 pesetas, engine men 3.5 pesetas, and boiler men 2.5 pesetas per day. Coal (which is of poor quality) costs 34 pesetas per ton at Linares and 37@38 pesetas at the mines. A branch railway connects the mines of Taylor & Co. with the smelter, although the transport of ore from the other mines is by donkeys and mule carts.

#### THE LEAD MARKETS IN 1901.

*New York.*—The American Smelting & Refining Co., which controls nearly the entire output of desilverized lead in the United States, was the dominant factor in the market throughout the year. Under its direction prices were fixed at a uniform rate which was regarded as fair to both producer and consumer, and it was the object of the company to maintain this schedule independent of foreign markets. As the normal supply of lead from domestic sources is greatly in excess of the home consumption, the policy outlined by the company could not be carried through without recourse to the plan of exporting the surplus or limiting the output. In the early part of the year when the quotations on the European markets were nearly on a parity with New York prices the former expedient was adopted. The foreign demand soon fell off and brought prices down to a level much below the company's schedule, so that exportation meant a loss. Arrangements were also made with the principal producers of lead ores to reduce their output, but not until royalties were promised them for the loss on contracts. Notwithstanding these expedients, the stocks held by the company had grown before the end of the year to large proportions and when the quotations on European markets fell to a point where importation to this country seemed likely, the policy was abandoned and the prices lowered. The producers of chemical and soft Missouri lead enjoyed a very prosperous year as the demand was good even at the high prices.

AVERAGE MONTHLY PRICES OF LEAD IN NEW YORK.

| Year.     | Jan. | Feb. | Mar. | Apr. | May. | June. | July. | Aug. | Sept. | Oct. | Nov. | Dec. | Year |

*London.*—The lead market opened in January at £16 5s. for soft foreign and about 2s. 6d. more for English. Trade was brisk at this figure, but later on in the month there was a considerable amount of free selling on American account,

which speedily brought values down to the neighborhood of £15. The fall was rapid that consumers were frightened off the market. When February started steady market for a few days induced a little better demand, but on the resumption of selling, prices again broke quickly, reaching £13 10s. before the close of the month. March commenced with spirited buying on the part of prominent dealers, while American and Continental selling ceased for the time, values consequently quickly recovering to £14 10s. As soon, however, as confidence was again established, there was a renewed attack on the market by Continental holders, which drove values to £12 15s.; but with a good demand from Russia and Germany they rose to £13 5s., which was about the closing price for soft foreign, English being worth about £13 7s. 6d. April again witnessed a slump caused by free arrivals, and £12 3s. 9d. was at one time accepted. This level attracted consumers and there was a recovery to £13 5s. for forward delivery, while spot stuff being plentiful, only fetched about 10s. discount below the price of distant metals. When a fair business had been put through, the Americans again became pressing with their sales, and ere the month was out prices fell to £12 5s., and this was the price at the beginning of May. American offerings were small, and this steadied the market to £12 10s., but on a resumption of cheap offers from that side, there was a set-back of £12 2s. 6d. June opened with a dull and neglected market; prices moved fractionally round about the previous values, the month ending at £12 7s. 6d. to £12 10s. for foreign and £12 10s. to £12 12s. 6d. for English lead. July commenced with a dull tone at about £12 8s. Buyers were not inclined to commit themselves to any extent, the consequence being that prices gradually drifted throughout the month, until £11 15s. was the ruling figure, and the month ended at about this price. August showed a little better demand at the beginning of the month, but this soon fell off, and values declined to £11 10s. They ultimately recovered fractionally to £11 18s. chiefly on speculative buying, and the exporters held for full prices. September witnessed a further improvement, and was apparent that consumers were very busy. Lead for prompt delivery was somewhat scarce, and the price of short deliveries at one time reached £12 12s. 6d. They fell off by about 2s. 6d. to 5s. before October, at the commencement of which month prices declined still further to £11 5s. This level induced a good inquiry and there was a rally to about £11 10s. to £11 12s. 6d. November was a flat month, owing to heavy arrivals of European and Australian metal, which caused decline to £11, the market practically closing at this figure. December began with a very poor demand, and with the large arrivals of metal and free selling from America and the Continent, values suffered almost daily, until at one time £12 2s. 6d. was touched for soft foreign, English being quoted £10 5s. Toward the end of the month the lower range of prices attracted a good deal more attention from consumers, who bought rather freely.

## WHITE LEAD, RED LEAD, LITHARGE AND ORANGE MINERAL.

The aggregate production of lead pigments during 1901 was slightly greater than in 1900, the increase being distributed among all varieties except litharge, of which a slightly smaller output was reported.

The production of red lead during 1901 was 13,103 short tons, valued at \$1,448,550, as compared with 10,098 short tons, valued at \$1,050,192, showing an increase of 3,005 tons and \$398,358.

The production of white lead during 1901 was 100,787 short tons, valued at \$11,252,653, as compared with 96,408 short tons, valued at \$9,910,742 in 1900, an increase of 4,379 short tons and \$1,341,911.

The production of litharge during 1901 amounted to 9,460 short tons, valued at \$979,586, as compared with 10,462 short tons, valued at \$1,067,124, a decrease of 1,002 short tons and \$87,558.

There were produced during 1901 1,087 short tons of litharge, valued at \$224,667, as compared with 825 short tons, valued at \$100,650 in 1900, showing an increase of 262 tons and \$124,017.

The detailed statistics of the production and imports of the various lead pigments are given in the subjoined tables:—

## UNITED STATES: PRODUCTION OF RED LEAD, WHITE LEAD, LITHARGE AND ORANGE MINERAL.

| Year.     | Red Lead.   |           | White Lead. |             | Litharge.   |           | Orange Mineral. |          |
|-----------|-------------|-----------|-------------|-------------|-------------|-----------|-----------------|----------|
|           | Short Tons. | Value.    | Short Tons. | Value.      | Short Tons. | Value.    | Short Tons.     | Value.   |
| 1897..... | 7,798       | \$744,709 | 105,804     | \$9,522,360 | 8,591       | \$773,190 | 477             | \$76,280 |
| 1898..... | 9,160       | 916,000   | 93,172      | 9,391,738   | 7,460       | 710,122   | 658             | 65,297   |
| 1899..... | 10,199      | 1,070,695 | 103,466     | 10,812,197  | 10,080      | 1,032,060 | 925             | 122,350  |
| 1900..... | 10,098      | 1,050,192 | 96,408      | 9,910,742   | 10,462      | 1,067,124 | 825             | 100,650  |
| 1901..... | 13,103      | 1,448,550 | 100,787     | 11,252,653  | 9,460       | 979,586   | 1,087           | 224,667  |

In addition to the products stated in the foregoing table, the United States Reduction & Refining Co., at Cañon City, Colo., reported an output of 2,500 short tons of "zinc-lead," valued at \$150,000. This pigment is a mixture of oxidized compounds of zinc and lead made by an oxidizing smelting of lead and zinc ores in a blast furnace of special design.

## UNITED STATES: IMPORTS OF RED LEAD, WHITE LEAD, LITHARGE AND ORANGE MINERAL.

| Year.     | Red Lead. |          | White Lead. |          | Litharge. |         | Orange Mineral. |          |

The following table shows that the difference in price between white lead in oil and pig lead in New York in 1901 was \$1.36, as compared with a difference of \$1.02 in 1900. Against this must be set the difference in the price of linseed

**ANNUAL AVERAGE PRICE AT NEW YORK OF CORRODING PIG LEAD AND WHITE  
LEAD IN OIL.**

| Year.     | Corroding<br>Pig Lead. | White Lead<br>in Oil. | Difference. | Year.     | Corroding<br>Pig Lead. | White Lead<br>in Oil. | Difference. |
|-----------|------------------------|-----------------------|-------------|-----------|------------------------|-----------------------|-------------|

oil, which varied from 50c.@82c. per gal. in 1901, and from 50c.@67c. per gal. in 1900. The price of linseed oil at the beginning of 1900 was 56c. per gal.; it sold as low as 50c. in September, and reached the highest point of the year, 67c., in July. Beginning with 56c. in January of 1901, the price advanced until it reached 82c. in July, and then declined until 50c. was reached in September, closing the year at 55c. The market price for pig lead in New York opened at 4.525c. and closed at 4.125c. The former price was maintained until December 17, when it dropped to 4.125c., and continued at this quotation for the remainder of the year.

**PROGRESS IN THE MANUFACTURE OF WHITE LEAD DURING 1901.**

BY PARKER C. MCILHINEY.

THE white lead industry in this country has not undergone any serious changes during the past year. The old Dutch process continues to produce the bulk of the product. It is estimated that about 92% of the white lead produced was made by the Dutch process, the other 8% being made by various quick processes. Of these the Carter process is still the most important.

Dahl's process, which is operated by W. J. Matheson & Co., of New York, was by a misprint in the last issue of THE MINERAL INDUSTRY, represented as resembling the Carter process, while, as a matter of fact, the process consists in treating metallic lead with acetic acid and air in such a way as to produce a solution of basic acetate of lead, which solution is then treated with carbonic acid in a separate operation, thereby precipitating the basic carbonate. The carbonic acid used is made by washing the flue gases from the boiler. The details of the operation are kept secret. The production of white lead by this process during 1901 was about 3,000 tons. The makers claim that during the past year the process has been improved so as to produce a denser lead, the specific gravity of the present product being about 6.3. The white lead now produced requires from 11 to 11.25% of oil in grinding, whereas the product formerly made required 14%, and was harder for the user to break up in oil.

The Bailey process has been taken up by the Union Lead & Oil Co., which completed a plant in Brooklyn, N. Y., early in 1902. The plant is designed to produce 12,000 tons annually. It is claimed by the company that the white lead made by the Bailey process is identical with the best Dutch lead, as it is produced by a process which is substantially the same as the Dutch except that on account of the subdivision of the lead and consequent exposure of large surfaces for corrosion, the time required for the corrosion is only three days, as compared with three months in the Dutch process. The specific gravity of the product is

given as 6·49. The company claims to have perfected the mechanical arrangements of the process in such a manner as to do away to a great extent with manual labor. The lead is run directly from the pot in which it is melted through a nozzle perforated with fine holes on to trays carried by a conveyor. The conveyor transports the trays to a corroding chamber and fills it automatically, one layer of trays above another. When the chamber is full carbonic acid is turned on from a gas holder and 2·5% acetic acid is injected with steam. The carbonic acid gas is generated by burning oyster shells and the shell lime thereby produced is stated to pay for the cost of manufacturing the gas. The carbonic acid is washed, first in a coke tower and then in a tower filled with iron sponge, both kept wet with water. The progress of the corrosion in the chamber is watched through suitable windows. The claim is made that the white lead does not require grinding at all but is simply stirred up in water and floated off. The Union Lead & Oil Co., in July, 1902, claimed to be producing white lead at the rate of 6,000 tons a year, the plant being in operation about one month.

The developments in other processes during the past year do not appear to have passed the experimental stage.

## RECENT IMPROVEMENTS IN LEAD SMELTING.

BY H. O. HOFMAN.

## INTRODUCTORY.

**New Publications.**—C. Schnabel's *Handbuch der Metallhüttenkunde*, Vol. I,<sup>1</sup> has appeared in a revised and enlarged edition. The general character of the work has remained the same. The chapter on lead has been enlarged from 184 to 216 pages; little, if anything, has been cut out; the additions are taken from publications which have appeared since the first edition of 1894.

C. and J. J. Beringer's "Text-Book of Assaying"<sup>2</sup> has appeared in its seventh edition. The favor with which this manual has been received can be judged from the fact that the first edition appeared in 1890.

**Lead-Amalgams.**—H. Fay and E. North, 2nd.,<sup>3</sup> have investigated the nature of lead amalgams. They find that there exists an amalgam,  $Pb_2Hg$ , which is soluble in and is isomorphous with lead; it therefore lowers the freezing temperature of lead when successively added to it. The compound is insoluble in mercury and therefore does not lower the freezing point of mercury when added to it. The behavior is represented in the reference by a fusibility curve, which shows that the diminished freezing points of lead all fall along a straight line, while the melting point of pure mercury remains unchanged.

**New Lead Mineral.**—W. H. Twelvetees<sup>4</sup> describes a new mineral—Petterlite—an oxychloride of lead which was found in the upper workings of the Britannia mine, Zeehan, Tasmania. The analysis shows:  $PbO$ , 74.04%;  $As_2O_3$ , 2.6%;  $P_2O_5$ , 2.1%;  $Sb_2O_3$ , 0.5%;  $Cl$ , 20%.

**Sampling Ores.**—F. W. Braun & Co.,<sup>5</sup> Los Angeles, Cal., has put in the market the Calkins gyrating laboratory pulverizer. It consists of an iron mortar with pestle operated by turning a handle supported by an arch over the mortar. The width of the apparatus is 16 in., the height, 13 in., the diameter of the ball of the pestle, 5 in.; the net weight is 61 lb., and the weight packed for shipment, 86 lb. It is claimed that with average hard ore, 75% of it will pass through a 60-mesh sieve after one minute's grinding.

The same firm<sup>6</sup> has placed on the market a small laboratory hand-crusher, called "Simplex." The machine may be adjusted to produce from 2-in. to 10-mesh material. The capacity is claimed to be large.

The "Calkins Umpire Ore Sampler"<sup>7</sup> is a continuous sampling machine consisting of two buckets, one above the other, revolving in opposite directions. Each bucket has a central cone from which four radial partitions extend to the sides, thus giving four sectoral divisions, of which two are closed and two open at the bottom. Of 16 lb. of ore fed into the machine, 8 lb. remains in the upper bucket, 4 lb. goes into the lower bucket and 4 lb. passes as the sample into the receiver below. The machine is 3 ft. 7 in. high and weighs 55 lb.; it is easily cleaned. The claims made for it are too great, since its use must be limited,

<sup>1</sup> Published by Springer, Berlin, 1900.<sup>2</sup> London, Charles Griffin & Co.; Philadelphia, J. B. Lippincott Co.<sup>3</sup> *American Chemical Journal*, 1901, p. 216.<sup>4</sup> *Engineering and Mining Journal*, July 20, 1901.<sup>5</sup> *Mines and Minerals*, June, 1901, p. 526.<sup>6</sup> *Mining and Scientific Press*, Dec. 7, 1901.<sup>7</sup> *Engineering and Mining Journal*, April 27, 1901.

as is the case with all continuous sampling machines. An improved form has recently been patented by A. C. Calkins.<sup>8</sup>

The editor of the *Mining Reporter*<sup>9</sup> is publishing a series of articles on sampling of ores which, it is stated, are compiled from the notes of a mining and mechanical engineer. The articles are excellent and will be reviewed in detail when finished. It is hoped that a reprint in pamphlet form will appear, that this valuable contribution to the important subject may be readily accessible to all men who have to deal with ores.

G. A. Overstrom patented<sup>10</sup> an intermittent mechanical sampler, the details of which are not given with sufficient clearness, either in text or sketch to make them quite intelligible. Other patents are those of G. D. Potter,<sup>11</sup> H. E. T. Haultain,<sup>12</sup> and J. Scobey.<sup>13</sup>

The "Coronet Rolls" of F. W. Braun & Co., Los Angeles, Cal.,<sup>14</sup> are 2.5 in. in diameter and 1.25 in. wide, made of hardened steel and run in phosphor-bronze boxes. Both rolls are operated by one crank; a feed-plate at the front facilitates the insertion of a small button and a second plate at the back, closely wiping the bottom roll, prevents the cornet from dropping on the floor. The net weight of the machine is 75 lb. and the weight, when boxed for shipping, 85 lb.

*Assay Furnace.*—D. Laird patented<sup>15</sup> a crucible assay furnace in which the air necessary for combustion is superheated by the waste gases of the furnace.

*Assay-Balance.*—W. Ainsworth & Co., Denver, Colo.,<sup>16</sup> has placed on the market a button-balance with 4-in. beam which is said to be well adapted for quick and accurate work.

*Assay of Lead Ores.*—R. W. Lodge<sup>17</sup> criticises the statement made by the editor of the *Engineering and Mining Journal* (December 22, 1900, p. 734) that iron sulphide, formed in assaying sulphurous ores, is oxidized and fluxed. He shows, as seen below, that the amount of matte which will separate out is governed by the amount of alkali added to the charge; in fact, that with a sufficient amount of alkali the whole of the matte will be held in solution or suspension. In the assay all the sulphur, however, does not combine with the iron and alkali, part of it is oxidized and passes off into the air.

The subjoined assays A and B prove the preceding statements:—

| Assay.           | A.     | B.       | Result.                                   | A.      | B.      |

<sup>8</sup> United States Patent No. 682,528, Sept. 10, 1901.

<sup>9</sup> *Mining Reporter*, "Notes on Sampling," Oct. 24, Nov. 28, Dec. 5, 12, 19, 26, 1901; and Jan. 16, 23, Feb. 6, 1902.

<sup>10</sup> United States Patent No. 674,035, May 14, 1901.

<sup>11</sup> United States Patent No. 679,574, July 30, 1901.

<sup>12</sup> United States Patent No. 680,526, Aug. 13, 1901.

<sup>13</sup> United States Patent No. 684,314, Oct. 8, 1901.

<sup>14</sup> *Engineering and Mining Journal*, April 6, 1901.

<sup>15</sup> United States Patent No. 671,558, April 9, 1901.

<sup>16</sup> *Engineering and Mining Journal*, Sept. 7, 1901.

<sup>17</sup> *Ibid.*, March 16, 1901.

The slag from assay A contained 6.73% and from B, 7.63% sulphide sulphur. In assay A, 8% and in B, 14% sulphur was oxidized and passed off into the air.

W. Lay<sup>18</sup> gives some interesting results of experiments made to study some phases of the assay of lead ores in the dry way. Fusions in a muffle with a reducing atmosphere and the following charge: ore, 10 g.; flux (sodium bicarbonate, 16 parts; potassium carbonate, 16; borax, 8; flour, 5), 30 g.; salt cover and two nails; gave the subjoined results:—

DURATION OF FUSION, FIFTEEN MINUTES.

| Antimony in Ore. | Lead in Ore. Wet Analysis. | Lead in Ore. Fire Assay. | Condition of Button Resulting from Fire Assay. |
|------------------|----------------------------|--------------------------|------------------------------------------------|
| 0.63             | 54.2                       | 53.6                     | No evidence of brittleness.                    |
| 0.90             | 55.7                       | 54.7                     | Slightly brittle.                              |
| 1.85             | 55.8                       | 54.9                     | Buttons crack under the hammer.                |
| 1.80             | 54.8                       | 54.8                     | Buttons crack under the hammer.                |
| 2.70             | 50.3                       | 51.0                     | Buttons crack under the hammer.                |
| 3.60             | 47.7                       | 48.5                     | Buttons crack under the hammer.                |

They show that antimony passes mainly into the lead button. Comparatively little lead is lost by volatilization. Analyses of slags of carefully conducted assays gave 0.62% Pb; the loss was also found to increase with the temperature, it being important to start at a low heat.

The following table gives the relative losses in lead by slagging and by volatilization:—

| Lead in Ore. Wet Analysis. | Lead in Ore. Fire Assay. | Difference between Wet and Fire Assays in Units of Lead. | Lead in Slag. Wet Analysis. | Weight of Slag from Fire Assay. (Approximate.) | Units of Lead Accounted for in Slag. |
|----------------------------|--------------------------|----------------------------------------------------------|-----------------------------|------------------------------------------------|--------------------------------------|
| 50.9                       | 49.8                     | 1.7                                                      | 0.62                        | Grams.                                         | 1.7                                  |
| 52.2                       | 50.7                     | 1.5                                                      | 0.53                        | 28                                             | 1.5                                  |
| 52.7                       | 51.1                     | 1.6                                                      | 0.47                        | 29                                             | 1.4                                  |
| 52.6                       | 51.0                     | 1.6                                                      | 0.53                        | 28                                             | 1.5                                  |

Mechanical losses occur by spirting, when the charge is fired too quickly. These are shown in the following table.

Charges of ore and flux same as before:—

| Lead in Ore. Time of Fusion, 75 Minutes. | Lead in Ore. Time of Fusion, 30 Minutes. | Lead in Slag by Wet Analysis. | Lead in Ore. Time of Fusion, 75 Minutes. | Lead in Ore. Time of Fusion, 30 Minutes. | Lead in Slag by Wet Analysis. |
|------------------------------------------|------------------------------------------|-------------------------------|------------------------------------------|------------------------------------------|-------------------------------|
| 53.6                                     | 51.0                                     | Average, 0.74                 | 49.4                                     | 47.1                                     | Average, 0.74                 |
| 54.5                                     | 52.9                                     | Average, 0.74                 | 61.2                                     | 59.3                                     | Average, 0.74                 |
| 51.0                                     | 50.1                                     | Average, 0.74                 | 53.0                                     | 51.0                                     | Average, 0.74                 |

P. R. Robert,<sup>19</sup> while smelting coppery lead ores from the Standing Elk mine, Bunker Hill, Nev., assayed his ores and mattes as follows: He dissolved in nitric acid, precipitated with sulphuric acid, filtered and washed with acidulated water, dried with precipitate, removed filter and burned it, added it to the precipitate in a porcelain annealing cup, charged with five times its weight of potassium cyanide and fused. When cool, he placed the cup in water which dissolved the salts leaving behind the lead as a metallic button.

<sup>18</sup> *Journal of the Canadian Mining Institute*, 1901, p. 224; *Canadian Mining Review*, 1901, p. 125.

<sup>19</sup> *Institution of Mining and Metallurgy*, 1900-1901, Vol. IX., p. 270.

*Silver and Gold Assays.*—H. Nissenson<sup>20</sup> compared the crucible and scorification methods of assaying in use at the main laboratory of the Stolberg and Westphalen Co. for determining the silver contents in Broken Hill concentrates. These contain Pb, 66 to 68%; Zn, 6 to 8%; SiO<sub>2</sub> etc., 10 to 12%; S, 12 to 14%, and Ag, 23 to 26 oz. per ton. The crucible assay is carried out in wrought iron crucibles; 25 g. ore are mixed in a warm crucible with 20 g. flux (3 parts sodium carbonate; 2, borax; 1, argols), covered with 60 g. of the same flux and melted in a crucible furnace. Slag and lead are poured separately, the lead button is weighed and then cupelled. In scorifying, 5 g. of ore are mixed with 10 g. of granulated lead and covered with 25 g. of lead; 2 g. of borax and about 2.5 g. of iron wire are added to the charge. The scorification assay always gave 3.8 oz. more silver per ton than the crucible assay. Upon examining the buttons from 150 scorification- and 30 crucible-assays, the author found the scorification-assay buttons to contain 1.316% Pb, 0.556% Bi, and 0.276% Cu, a total of 2.148% impurities, and the crucible-assay buttons, 0.52% Pb and traces of Cu. The concentrates contain hardly a trace of bismuth but some was found to be present in the assay lead. The higher result of the scorification-assay is to be attributed to the impurities of the assay lead becoming concentrated in the silver button. In order to test these results, similar buttons were examined at the Mulden Works, Freiberg, Saxony, by A. Schertel,<sup>21</sup> who found them to contain 98.26% silver by the Gay-Lussac titration method and 98.68% silver by the gravimetric method. The filtrate of the second assay showed lead and bismuth to be present, but no copper was found.

Truchot<sup>22</sup> advocates the following method for determining silver in chalcopyrite: Roast the ore, dissolve in mixture of 150 c.c. of nitric acid (sp. gr. 1.42), 50 c.c. of hydrochloric acid (sp. gr. 1.18) and 100 c.c. of sulphuric acid (sp. gr. 1.58) in a dish, evaporate to disappearance of sulphuric acid fumes, add water and sulphuric acid, dissolve, transfer to breaker, dilute to 1.5 liters, add solution of 4.5 g. of salt, allow to settle in the warm over night, filter, wash, dry and burn filter, scorify the ashes, etc.

E. A. Smith<sup>23</sup> gives an extended review of the assaying of complex gold ores discussing the general principles involved and giving some detail instructions as to the treatment of nine different classes of ores. Basic oxidized ores are best treated by direct fusion in crucibles, special attention having to be given to the amount of reducing agent necessary, and to the addition of metallic iron for ores containing a small percentage of pyritic material. A charge for moderately basic ores (30% Fe<sub>2</sub>O<sub>3</sub>) is: ore, 50 g.; litharge, 40 g.; charcoal, 2.5 g.; borax, 20 g.; soda, 30 g., salt cover. One for very basic ores: ore, 50 g.; litharge, 50 g.; charcoal, 4 to 6 g.; borax, 30 g.; soda, 10 to 15 g., sand or glass, 10 to 20 g.; salt cover. With ore containing small quantities of copper or antimony, the litharge should be increased to from 60 to 70 g. With ores containing lime, alumina or zinc oxide, a mixture of 40 g. borax and 20 g. soda with 50 g. ore usually gives

<sup>20</sup> *Berg- und Huettenmaennische Zeitung*, Vol. LIX., 1900, p. 572.

<sup>21</sup> *Ibid.*, Vol. LX., 1901, 340.

<sup>22</sup> *Engineering and Mining Journal*, Nov. 30, 1901.

<sup>23</sup> *Institution of Mining and Metallurgy*, 1900-1901, Vol. IX., 315-322.

results; in the presence of barium sulphate or calcium phosphate an addition of from 10 to 20 g. fluorspar to the 50-g. ore charge may be necessary.

With very rich ores, it is necessary to clean the slag by mixing it, roughly powdered, with litharge, 30 g.; charcoal, 1.5 g.; soda, 10 g. and remelting it. Pyritic ores (containing mainly pyrites) are best first roasted and then treated as basic ores. Any loss of gold in roasting is due to want of care in conducting the operation and not to the operation itself. Direct fusion with the addition of metallic iron is justifiable only when the ores do not contain over 30% pyritic material. A slag of 50 g. quartz fused with soda will hold in solution from 10 to 12 g. iron sulphide. A good charge is: ore, 50 g.; red lead, 40 to 50 g.; charcoal, 2 g.; borax, 10 to 15 g.; soda, 40 to 50 g.; metallic iron. Oxidation with niter, which is more expeditious than roasting, ought to be applied only when the percentage of sulphurets is small. One g. iron pyrites requires 2 to 2.5 g. niter; 1 g. mispickel, copper pyrites, fahlore or blende, 1.5 to 2 g.; 1 g. antimonide, 1.5 g.; and 1 g. galena, 0.66 g. Arsenical ores are best roasted and then assayed as basic ores. An addition of a small amount of potassium cyanide to the crucible charge aids in the decomposition of arsenates. Antimonial ores are generally oxidized with niter, as roasting is connected with difficulties owing to the ready fusibility and volatile nature of stibnite. A preliminary assay will have to give the reducing power of the ore from which the amount of niter necessary can be determined.

Cupriferous ores when rich in copper (over 30%) are best assayed by the combined wet and dry methods, a suitable flux for the residue of 30 to 50 g. ore is: red lead, 30 g.; charcoal, 1.5 g.; soda and borax up to 30 g. Direct fusion with ores under 30% Cu gives good results with the following charge: ore, 10 to 50 g.; red lead, 200 to 300 g.; charcoal, 1.5 to 3.5 g.; sand or glass, 10 to 25 g. For fusion after a preliminary roast, 10 to 50 g. ore are charged with red lead, 100 g.; charcoal, 3.5 g.; soda, 20 to 30 g., and borax, 15 to 30 g. With rich ores the slags should be remelted with fluxes (*see above*). Auriferous antimonial copper ores give good results with: ore, 30 g.; red lead, 150 g.; soda, 120 g.; niter, 18 g. Scorification with cupriferous ores is satisfactory, if the ores are rich enough in gold to allow the adoption of this method.

Ores with galena are best treated by direct fusion with metallic iron. Ores with blende ought first to be roasted and then treated as basic oxidized ores with an increase of the proportions of borax and soda; in exceptional cases an addition of fluorspar may be necessary.

Telluride ores ought always to be treated by direct fusion in the crucible using large amounts of litharge and ordinary fluxes. The following charge serves for most telluride ores: ore, 50 g.; red lead, 50 to 200 g. (according to the amount of tellurium present); charcoal, 1 to 2 g.; soda, 50 g.; borax, 20 g.; sand, 10 to 30 g.; salt cover. For very rich ores the following charge should be used: ore, 10 g.; red lead, 10 to 150 g.; charcoal, 1 g.; soda, 50 g.; sand, 5 to 10 g.; salt cover.

Bismuth ores are treated by direct fusion as basic ores, but in order to carry the bismuth into the slag it is necessary to have a readily fusible slag, hence comparatively large amounts of borax and soda ought to be used. A piece of iron

is added to the charge to decompose any sulphide of bismuth, as bismuth-bearing ores ought not to be roasted on account of the volatility of bismuth. Scorification is unsatisfactory.

For scorification the author recommends the following proportions:—

| Character of Ore. | For One Part of Ore.      |                       | Character of Ore.         | For One Part of Ore.      |                       |
|-------------------|---------------------------|-----------------------|---------------------------|---------------------------|-----------------------|
|                   | Parts of Granulated Lead. | Parts of Borax Glass. |                           | Parts of Granulated Lead. | Parts of Borax Glass. |

*Assay of Gold-Silver-Platinum Alloys.*—R. Oehmichen<sup>24</sup> recommends the following method for separating platinum, gold and silver collected in the button in cupelling: Boil the button with sulphuric acid until the cessation of bubbles of gas shows that most of the silver has been dissolved; cool, decant the silver solution, boil the residue twice for five minutes with nitric acid (sp. gr. 1·3), wash, dry, and weigh the gold-platinum residue. If the amount of platinum is smaller than that of gold, in quart and treat with nitric acid several times, when the residue will be insoluble gold (plus any iridium that may be present). If the amount of platinum is larger than that of gold (alloy with 50 to 100 mg. of gold), dissolve in nitro-hydrochloric acid (filter off any iridium), precipitate the gold with ferrous sulphate, filter, dry, ignite, cupel adding silver necessary for inquartation, part the silver-gold button and weigh the gold. The platinum is found by difference, but may be determined by precipitating with zinc, filtering, cupelling the ashes with lead adding three times the weight of silver, dissolving the button in sulphuric acid and weighing the insoluble residue—the platinum.

*Determination of Arsenic, Antimony, Tin and Bismuth.*—Liebschütz<sup>25</sup> advocates the following method of determining arsenic, antimony, tin and bismuth in refined lead. Place 100 g. of flattened and cut-up sample in lipped beaker of 1·3 liters capacity, cover with 220 c.c. boiling water, add 100 c.c. nitric acid (sp. gr. 1·42) and 10 c.c. iron nitrate (20 g. iron to the liter); when effervescence quiets down, complete solution in one hour by warming; should any lead nitrate separate out, add water. Dilute the solution with water to one liter, add a few drops of a saturated salt solution, then neutralize, drop by drop, with caustic soda until a light red precipitate forms which darkens upon stirring. When the precipitate has settled, decant the almost clear solution into a large filter in a 5-in. or 6-in. funnel leaving the precipitate behind; fill the beaker with boiling water, stir and decant the clear solution, fill beaker again adding a few drops of caustic soda until the suspended light-red precipitate turns brick-red. In the meantime wash filter twice with hot water filling it completely and then decant solution through the filter. Add to the precipitate in the beaker a few c.c. of a 50-per cent. solution of tartaric acid and a few c.c. of hot dilute hydrochloric acid, place beaker under funnel and dissolve any precipitate on the filter with the same solvents, wash with hot water and moisten the filter

<sup>24</sup> *Berg- und Huettenmaennische Zeitung*, 1901. p. 137.

<sup>25</sup> *Engineering and Mining Journal*, Aug. 10, 1901.

on and off with hydrochloric acid. Dilute solution to one liter and precipitate with hydrogen sulphide; the separation of the lead is assisted by the addition of a little ammonium sulphide. Collect sulphides on a double filter, 15 cm. in diameter, washing until all iron salts have been separated. Remove the bulk of the sulphides with wash-bottle into a 250-c.c. beaker, dissolve what remains with 20 c.c. of ammonium sulphide into the same beaker and wash with hot water. Warm the beaker for half an hour, pass solution through the same filter and wash with water containing a little ammonium sulphide. Now precipitate from the filtrate, arsenic, antimony and tin as sulphides by acidulating with hydrochloric acid. In the absence of tin, treat the washed sulphides with ammonium carbonate and titrate the dissolved arsenic with 0.01 iodine after neutralizing with acetic acid and adding starch to the faintly acid solution (1 c.c. 0.01 iodine = 0.00023 arsenic). Dissolve the antimony sulphide in 25 c.c. of hydrochloric acid at a low temperature and titrate with iodine in the presence of tartaric acid and sodium bicarbonate, using starch as an indicator. In the presence of tin, use Clark's oxalic-acid method or the electrolytic method. Place the lead and bismuth remaining on the first filter into a small dish, incinerate at a low temperature, moisten ashes with nitric acid, evaporate carefully and calcine; now add 5 c.c. of sulphuric acid, evaporate to white fumes, take up with water, filter and wash with dilute sulphuric acid. Add to the bismuth solution 12 in. of piano wire and 5 c.c. of hydrochloric acid and boil about one hour, when all the bismuth will have been precipitated as a black sponge or a black powder, if little was present. Detach the bismuth from the wire with a glass rod, decant the solution, cover the bismuth with hot water, remove the wire, decant wash-water, wash bismuth with alcohol bottle into a small porcelain crucible, remove excess of alcohol with a pipette and dry and weigh the metallic bismuth.

*Analysis of Slags.*—C. H. Joüet<sup>26</sup> publishes an outline for the analysis of slags and cinders to which reference should be made for details.

*Purchasing of Ores.*—The following schedule of the American Smelting & Refining Co.<sup>27</sup> for the purchase of silver ore is quoted to show the manner in which the value of an ore is computed. Owing to the wide extent of territory covered by this company and the resultant variable factors of freight, fuel, labor, etc., no fixed schedule is adhered to, the price paid by them for ores being usually arranged by private contract. The miner who enters into a contract with the company is required to sell to it his entire product up to a maximum of 200 tons per month which the company agrees to buy, unless it is not able, without serious loss to itself, to buy a particular combination of ores, when the miner is given the privilege to dispose of his ores otherwise during the period of suspension. The company agrees to pay for silver 95% of the value at New York; for gold, \$19 per oz., if the ore contains 0.05 oz. or more per ton; and for lead 90%, either at the price agreed upon by a majority of the Cœur d'Alène miners, or at the actual average daily New York quotation of the previous week, less 12.5c.

<sup>26</sup> *School of Mines Quarterly*, Jan., 1901, p. 140.

<sup>27</sup> *Engineering and Mining Journal*, May 11, 1901.

per cwt. Excess-iron is to be paid for at the rate of 15c. per unit, and no charge is to be made for excess-silica; zinc goes free up to 10%; above that limit, 50c. is to be charged for each unit. From the gross value of the ore thus computed, \$17 is to be deducted with ores, the net value of which does not exceed \$20 per ton; \$18.50 for ores of net value between \$20 and \$35; and \$20 for ores of net value of \$35 and over. The net value is the difference between gross value and charges. The charges are based on a railroad freight of \$11 per ton on ores valued at \$50 and over, and \$10 on ores valued at less than \$50 for full metal content. Any reduction or increase in freight rates is to be deducted from or added to the above graduated charges, as the case may be. If during the contract the price of lead becomes less than \$3.50 per cwt., the treatment charge is to be reduced \$1; if, on the other hand, the price of silver exceeds 65c. per oz., one-third of this excess value is to be deducted from the price of silver used in the settlement for the ore.

*Importation of Lead Ores.*<sup>29</sup>—The United States Board of General Appraisers has decided in relation to Mexican ores, carrying antimony and lead, that were treated at the Guggenheim Works at Perth Amboy, N. J., that the valuation of the ores in regard to free importation is to be based on the assays made in accordance with the Treasury regulations and not on the actual quantity of metal recovered by smelting and refining. The law requires that 90% of the metal in the ore treated in bond shall be exported.

*Lead in Arkansas.*—Branner<sup>30</sup> discusses briefly the history of lead smelting in Arkansas. The first lead smelter is said to have been erected on West Sugar Loaf Creek in 1851 or 1852. No mention is made of any lead ore being smelted in the State at present.

*Lead in Belgium.*—A. Firket<sup>31</sup> reviews the present state of the metallurgy of argentiferous lead in Belgium. There are in operation to-day four plants: Sclaigneaux, at Seilles; Bleyberg, at Montzen; Overpelt, at Overpelt and Hoboken-les-Anvers, at Antwerp. They produced in 1898, 58,390 metric tons of lead, 115,802 kg. of silver, and 233 kg. of gold. The materials treated in 1898 consisted of 548 tons of Belgian ores, 18,261 tons of foreign ores, 35,274 tons of lead-bearing residue from zinc-smelting furnaces, lead sulphate from chemical factories, metallic lead collected from the foundation flues of iron blast furnaces, and of 38,900 tons of imported argentiferous lead.

Galena ores are mixed with lead sulphate and flue-dust, and are roasted, the heat being raised sufficiently to agglomerate the roasted ore. Lead ashes are mixed with 10% lime and bricked. The two form the ores for the blast furnaces, which are small. The base bullion produced contains Cu, 0.2%; Sb, 0.7%; Ag, 46 to 58 oz. per ton; the matte, Pb, 10 to 12%; Ag, 9 to 12 oz. per ton; Zn, 4.3%; Cu, 1.9%; Sb, 1.07%; As, traces; S, 21%; Si, 4%; Fe, 48%; Ca, 1%; the slag, Pb, 1 to 1.5%; Ag, 0.5 to 0.6 oz. per ton; Zn, 6.5%; S, 2.2%; Si, 37%; Fe, 23%; Ca, 17%. The flue-dust contains PbSO<sub>4</sub>, 55 to 60%; ZnO

<sup>31</sup> *Annales des Mines de Belgique*, 1901, p. 237.

and  $\text{ZnSO}_4$ , 7 to 10%; Ag, 8 to 11 oz. per ton. The base bullion is Pattinsonized, the rich lead with 300 oz. silver to the ton is cupelled.

The plant of *Sclaigneaux* (Seilles) has 13 roasting furnaces, 16 blast furnaces, two reverberatory smelting and four reverberatory melting furnaces, 22 Pattinsonage kettles, two cupelling furnaces, one silver melting furnace and 12 coking ovens. The following analyses give the general character of the ores treated:—

Galena ores are roasted and partly agglomerated; in roasting lead ashes the heat is raised to complete fusion at the fire-bridge; both form part of the blast furnace charge. The blast furnace slag has the following composition: Fe, 40.83%;  $\text{SiO}_2$ , 29.33%;  $\text{CaO}$ , 11.4%;  $\text{MgO}$ , 1.44%; Zn, 4.25%; S, 1.86%; Pb, 0.5%; Ag, 0.0008%; As, traces. The base bullion averages: Ag, 0.11 to 0.18% (32 to 55 oz. per ton); Fe, 0.09%; Sb, 0.997%; As, 0.0012%; Cu, 0.0922%. It is softened in a reverberatory furnace and desilverized by means of the Parkes process with Roessler-Edelmann improvements, the zinc being charged with 0.5% of aluminum; the good effect of this addition is neutralized by the presence of 0.1% Cu or 0.05% As or 1% Sb. An analysis of liquated zinc-crust had the following composition: Pb, 86%; Ag, 1.7 to 2.5%; Zn, 10.5%; Cu, 0.667%; As, 0.045%; Sb, 0.4%; Fe and Cd, traces.

The silver produced at the works is .995 fine, the difference being made up by bismuth, lead, copper and nickel. The market lead has the following composition: Pb (by difference), 99.985%; Fe, 0.01%; Sb, 0.004%; Ag, 0.001%; Zn, trace.

The plant of *Hoboken-les-Anvers* is principally a refinery in which base bullion is desilverized by the Parkes process. The bullion forms 93 to 94% of the material treated, the other 6 to 7% being lead-bearing residues from zinc smelting furnaces and zinc works. The plant has two blast furnaces, 10 softening furnaces, eight roasters, seven reverberatory smelting furnaces, 21 desilverizing kettles (17 small and four 50-ton), nine liquation pots, four retorting furnaces, five cupelling furnaces, one silver refining furnace, and one furnace for roasting coppery drosses.

The base bullion received is classed under heads A and B.

| Class. | Pb.      | Sb.        | As.    | Cu.        | Ag.                      | Au.                          |

| A..... | 98 to 99 | 0.1 to 0.5 | Trace. | 0.1 to 0.5 | Oz. per Ton.<br>29 to 87 | Oz. per Ton.<br>Trace to 0.6 |
| B..... | 90 to 92 | 5 to 6     | 2 to 3 | 0.5 to 1.0 | 29 to 145                | 0.6 to 2.0                   |

The following analyses show the character of the residues from zinc smelting furnaces and of the sweeps:—

|           | Pb.      | Cu.      | Sb.        | As.      | Fe.  | Fe <sub>2</sub> O <sub>3</sub> . | Zn. | SiO <sub>2</sub> . | Al <sub>2</sub> O <sub>3</sub> . | CaO.   | Ag.                          | Au.                   |
|-----------|----------|----------|------------|----------|------|----------------------------------|-----|--------------------|----------------------------------|--------|------------------------------|-----------------------|
| Residues. | 44       | Traces.  | 0.2        | 0.6      | 15.9 | 7                                | 6.6 | 28.5               | 7                                | 2.3    | Oz. per Ton.<br>0.05 to 0.08 | Oz. pr. Ton.<br>Trace |
| Sweeps... | 0.1 to 1 | 0.9 to 2 | 0.1 to 0.3 | 0.5 to 1 | 7    | 30 to 35                         | 1   | 50 to 60           | 5 to 7                           | 1 to 5 | 1 to 3                       | 0.15 to 0.18          |

Base bullion, A, is softened in a reverberatory furnace. The dross forms 5% of the weight of the charge and is liquated in a separate furnace, giving liquation dross with 10% copper which goes to the blast furnace; the softening skimmings average Pb, 50 to 65%; Sb, 15 to 28%; As, 0.1 to 0.5%; Ag and Au, 29 to 87 oz. per ton.

Base bullion, B, is treated in a liquating furnace giving a dross of the following composition: Pb, 67 to 70%; Cu, 14 to 16%; Sb, 2 to 4%; As, 5 to 8%; SiO<sub>2</sub>, 4 to 6%; Al<sub>2</sub>O<sub>3</sub>, 0.8 to 1.2%; Fe, 0.5 to 2%; Ag, 58 to 116 oz. per ton; Au, 0.58 to 1.45 oz. per ton; it then goes into a softening furnace similar to one for bullion, A.

The skimmings from base bullions A and B are mixed with coal and melted in a reverberatory smelting furnace giving purified skimmings (to be smelted in the blast furnace for hard lead with 20 to 30% Sb) and base bullion. Zinc residues and sweeps are mixed with sand and limestone and then melted down on the hearth of a reverberatory roasting furnace before they go to the blast furnaces. The details of blast furnace work have little general interest. The following analyses show the compositions of the products: Slag—SiO<sub>2</sub>, 30%; FeO, 35%; CaO, 12%; Al<sub>2</sub>O<sub>3</sub>, 10%; Pb, 1%; Zn, 10%. Matte—Pb, 20 to 25%; Cu, 25 to 30%; Fe, 30 to 35%; S, 10 to 20%; Ag, 0.1 to 0.2%. Speise—As, 15 to 25%; Cu, 25 to 30%; Fe, 30 to 40%; Pb, 10 to 15%; Sb, 5 to 10%; Ag, 0.1 to 0.2%. Base bullion—Pb, 94 to 96%; Cu, 0.2 to 2%; Sb, 1 to 2; As, 0.1 to 0.5; Ag, 87 to 145 oz. per ton. This is classed as B,

en the dross obtained in liquating has been freed from adhering lead by a arate sweating operation. It contains about 30% Cu, is ground, roasted a reverberatory furnace and treated with sulphuric acid; the resulting copper phate is crystallized and sold as blue vitriol. The antimony skimmings are ated as outlined above. The details of the Parkes process are similar to the rk carried on elsewhere. The following analyses deserve to be recorded. ld crust: Au, 0.02 to 0.025%; Ag, 2 to 4%; Pb, 75 to 80%; Zn, 10 to 15%. ld retort-bullion: Au, 0.026 to 0.03%; Ag, 3 to 5%; Pb, 95 to 96%; , 0.8 to 1.5%. Zinc crust: Ag, 8 to 10%; Pb, 65 to 75%; Zn, 15 to 20%. lver retort-bullion: Ag, 18 to 20%; Pb, 80 to 82%; Zn, 0.05 to 1%. Re- ed lead: Pb, 99.9903%; Ag, 0.0004%; Au, traces; Sb, 0.0030%; As, 0.0005%; , 0.003%; Fe, 0.0008%; Si, traces; Cu, 0.0015%; Ni and Co, 0.0005%. ides from steaming desilverized lead: PbO, 83 to 87%; ZnO, 12 to 16%.

The plant at *Overpelt* treated in 1898, 1,000 tons imported lead ores, 11,600 ns leady material, and 500 tons imported base bullion. The ores before going the blast furnaces are slag-roasted. The roaster-bed has the following mposition: Pb, 33.9%; Cu, 0.85%; Ni and Co, 0.35%; As, 2.1%; Ag d Au, 0.04%; FeO, 26.30%; MnO, 1%; Zn, 6.6%; S, 1%; Al<sub>2</sub>O<sub>3</sub>, 4.18%; O, 6.8%; MgO, 0.3%; SiO<sub>2</sub>, 16.54%. The ore-beds show: Pb, 22 50%; Cu, 0 to 2%; Ni and Co, 0 to 1%; As, traces to 2.5%; Ag and , 0.005 to 0.054%; Fe and Mn, 14 to 27%; Zn, 3 to 13%; S, 1 to 5%; O<sub>3</sub>, 2.5 to 10%; CaO, 3 to 10%; MgO, 0 to 2%; SiO<sub>2</sub>, 12 to 33%.

The following analyses of blast furnace products are of interest: Slag: 27.85%; MnO, 4.74%; PbO, 0.78%; ZnO, 6.32%; Cu<sub>2</sub>O, 0.23%; 2.70%; CaO, 13.90%; MgO, 3.18%; Al<sub>2</sub>O<sub>3</sub>, 2.33%; SiO<sub>2</sub>, 27.96%. Base lion: Pb, 98.78%; Ag and Au, 0.14%; Cu, 0.19%; Sb, 0.72%; As, 0.08%; 0.08%; Fe, 0.04%. Matte: Cu, 4.85%; Ni and Co, 0.7%; Fe, 57%; , 8%; Ag, 0.02%; Zn, 6.5%; S, 16.8%; Sb, 1%; As, 3%. Speise: Cu, 3%; and Co, 5.1%; Fe, 55%; Pb, 1.9%; Ag, 0.017%; Zn, 2.5%; S, 3%; . 5.9%; As, 23.6%.

The market lead obtained by the Parkes process is of a high grade: Pb, 99.963 99.987%; Ag, 0 to 0.0005%; Sb, 0.008%; As, traces to 0.003%; Bi, 0.0047%; 0 to 0.0004%; Fe, 0.0023%; Cu, 0.0005%; Ni and Co, 0 to 0.0003%.

*Lead in Greece.*—Cordella,<sup>22</sup> in a general paper on the Mineral Resources of eece, reviews briefly the history of the smelting of lead slags and residues of Ancients and gives a summary of the present state of the lead industry which mainly a local interest. It may be stated that the ores treated are arsenical, ing a flue-dust with As, 35%; Pb, 27% and Ag, 8.8 oz. per ton. The smelt- plant Laurion produces annually 2,000 tons of speise which is not worked up. ontains: Cu, 2%; As, 27.26%; Sb, 1.04%; Fe, 57%; Pb, 2.5%; Mn, 0.22%; 1.5%; S, 5.75%; Ni, 0.16%.

*Lead-Smelting at Bunker Hill, Nev.*—P. R. Robert<sup>23</sup> records some experi- es in smelting in a blast furnace coppery lead ores from the Standing Elk

<sup>22</sup> *Zeitschrift fuer das Berg-, Huetten- und Salinenwesen im Preussischen Staate*, 1901, p. 365.

<sup>23</sup> *Institution of Mining and Metallurgy*, 1900-1901, Vol. IX., 262-266.

The slag analysis gave:  $\text{SiO}_2$ , 41%;  $\text{FeO}$ , 21%;  $\text{CaO}$ , 20%;  $\text{MgO}$ , 8.6%;  $\text{Al}_2\text{O}_3$ , 0.7%;  $\text{PbO}$ , 1.3%;  $\text{CuO}$ , 0.7%. Its specific gravity ranged from 3.2 to 3.6. The cost of smelting was:—

[The U. S. money equivalents of these figures are approximately \$3.65 and \$2.05 a ton.]

**Roasting of Ores.**—In the United States Circuit Court, District of Colorado, Judge Hallett<sup>35</sup> decided (August 1, 1901) that the Pearce and Ropp furnaces were infringements on the Brown furnace.

**Mechanical Reverberatory Roasting Furnaces.**—R. F. Pearce<sup>36</sup> has patented a multiple-hearth mechanical reverberatory roasting furnace, similar in principle to his Turret-furnace. The main points of interest are the manner of supporting the main walls of the hearths (cantilevers and truss-rods, rising at an angle, connecting the anchor-plates with the central vertical column) and the fact that the roof of a lower hearth forms the base of the upper hearth.

B. Hall patented<sup>37</sup> a mechanical reverberatory roasting furnace with stationary hearth resembling in principle the Brown straight-line furnace in which the return passage of the rakes is on an over-head rail. The main differences appear to be the manner of supporting the roof and a liquid seal which is to make it impossible for gases and fumes from the furnace to enter the chamber in which run the trucks pulled by the wire rope, and for air to enter the furnace when it is not wanted.

E. P. Parnell patented<sup>38</sup> a continuous mechanical reverberatory furnace with stationary hearth and traveling rakes.

J. A. Bentley's patent<sup>39</sup> is similar in principle.

J. Roger patented<sup>40</sup> a mechanical feeder for roasting furnaces; a feed screw, tapering from the ore-receiving to the opposite end, is imbedded in the hearth parallel to its width; revolving, it empties an ore-hopper outside of the furnace, elevates the ore onto the hearth from below and at the same time spreads it.

**Muffle Roasting Furnaces.**—C. J. Best patented a muffle roasting furnace<sup>41</sup> with inclined stationary hearth down which the ore is to glide and undergo the desired chemical changes.

H. Carmichael patented<sup>42</sup> a mechanical revolving muffle-roasting furnace, consisting of an inclined revolving larger cylinder to the lower end of which is attached a smaller one heated from a fire-place. The ore fed mechanically into the upper cylinder is to give up most of its sulphur, etc., there, when passing through the lower cylinder the sulphates, etc., are to be decomposed and travel-

<sup>35</sup> *Engineering and Mining Journal*, Sept. 7, 1901.

<sup>36</sup> United States Patent No. 671,071, April 2, 1901.

<sup>37</sup> United States Patent No. 677,510, July 2, 1901.

<sup>38</sup> United States Patent No. 685,344, Oct. 29, 1901.

<sup>39</sup> United States Patent No. 585,903, Nov. 5, 1901.

<sup>40</sup> United States Patent No. 677,701, July 2, 1901.

<sup>41</sup> United States Patent No. 674,594, May 21, 1901. [1901.]

<sup>42</sup> United States Patent Nos. 676,417 and 676,418, June 18,

ing beyond the fire-place in the cylinder, the ore is to cool giving up its heat to the incoming air-current.

A. P. O'Brien<sup>43</sup> patented some improved form of the well-known McDougal or Herreshoff furnace.

Another improved form is that of S. T. Wright.<sup>44</sup>

J. P. Wetherill patented<sup>45</sup> a muffle roasting furnace in which admission of air and withdrawal of sulphurous gases in different parts of the furnace can be regulated to suit conditions.

A. S. Partridge patented<sup>46</sup> a muffle furnace.

A peculiar roasting furnace was patented by G. D. Burton.<sup>47</sup>

J. B. Bridgewater patented<sup>48</sup> a door for ore roasting furnaces which slides up and down, being held in place by pins projecting from an iron casing.

A combined roaster and smelter has been patented by P. Kirk.<sup>49</sup>

*Cooling Ores.*—J. Jacobs patented<sup>50</sup> a car for cooling ores, containing pipes in which water or some other cooling medium is to circulate.

*The Blast Furnace.*—J. W. Nesmith patented<sup>51</sup> an improved form of his combined water- and air-jacket.<sup>52</sup>

A peculiar form of blast furnace has been patented by J. L. Wells.<sup>53</sup>

H. Kochinke<sup>54</sup> has published a very instructive paper on silver-lead blast furnaces. The leading facts have been brought together in the accompanying table. The furnaces are broadly of two types. The European continental furnace is circular, water-jacketed, has an internal crucible and a bottom- or siphon-tap; the American furnace is oblong, is water-jacketed, it also has the internal crucible, but always a siphon-tap. In circular furnaces the diameter at tuyeres has rarely exceeded 4.9 ft. At the Freiberg smelting works it was found that charges running low in lead could still be smelted in a furnace having a diameter of 6.6 ft.; at Braubach, Pertusola, Tarnowitz and Mazarron, with charges rich in lead, the diameter has been successfully increased to 7.9 ft. A circular furnace of 6.56 ft. in diameter represents an area of 33.82 sq. ft., an oblong furnace, 3.38×9.93 ft. has the same area. The circumference of the circular furnace is 20.7 ft., while that of the oblong furnace is 26.7 ft., the circumferences of the two furnaces of the same areas are as 3:4, which is, of course, in favor of the circular furnace, beside the many other advantages that it has over an oblong furnace. It should be remembered, however, that the European continental furnaces are usually charged with fritted or slag-roasted ore and large quantities of slag, while American furnaces are fed with much raw ore, often fine, and relatively little slag and lead flux. The experiment of running a circular blast furnace of large diameter in Colorado a few years ago proved a bad failure. The small diameters of tuyeres, the low tuyere-ratio and low pressure blast of European furnaces, when contrasted with American fur-

of interest. In connection with this, the low fuel consumption of the furnaces is noticeable. Whether this be due to the easy character of the ore or to the better proportioning of blast is still an open question.

MODERN LEAD BLAST FURNACES.

Movable tapping hearth (b) 66% roasted sulphide ore and 33% raw carbonate ore.

Modda<sup>55</sup> suggests that to obviate the difficulties encountered in smelt-lead ores rich in zinc, arsenic and antimony, the siphon- or bottom-d be closed and an external crucible attached with trapped blast to of the furnace and the melted masses allowed to flow continuously ore-hearth, where they can separate and be tapped.

<sup>55</sup> Engineering and Mining Journal, Sept. 7, 1901.

**Blast-furnace Elevator.**—Clemmer<sup>56</sup> gives an illustrated description of an elevator for smelting plants. It is designed to raise 6,000 lb. to a height of 19 ft. 8 in. with steam, water or air at a pressure of 60 lb.

**Blast-furnace Stack.**—W. Magman<sup>57</sup> describes and illustrates the wood smelter stack built in six weeks in 1897 by the Compañía Minera de Peñoles at Mapimi, Durango, Mexico, at a cost of \$10,000 (Mexican). A brick stack would have cost four times as much. The stack is 180 ft. high and 10 ft. square, and is constructed of ordinary 1-in. matched flooring lumber and lined on the inside with No. 22 corrugated roofing iron. The bracing is built mainly of 4×6-in. and 6×6-in. timber, some 8×8-in. timber being used in some parts.

**Graphical Calculation of Blast-furnace Charge.**—E. A. Hersam<sup>58</sup> gives a simple and easy method for the use of the tri-axial diagram in the calculation of slags which will be of interest to those who prefer graphical to algebraic methods of calculating charges.

**Rotary Blowers versus Blowing Engines.**—The replacement of rotary pressure blowers by blowing engines for furnishing the necessary air to lead blast furnaces and matting furnaces is receiving much consideration.<sup>59</sup> In former times with a blast pressure of from 8 to 12 oz., rotary pressure blowers of the Blake and Root type did very satisfactory work. When the pressure was raised to 40 oz. and sometimes even to 48 oz., the matter assumed a different aspect.

A. Raht,<sup>60</sup> for example, tested the volumetric efficiency of a rotary pressure blower by closing the discharge opening ("closed discharge"), connecting a pressure gauge with the closed delivery-pipe and gradually speeding up the blower. The gauge could be made to register only 10 lb. pressure, thus showing that the blower would not deliver air against a pressure of 10 lb. At 4 lb. pressure, the loss in blast appeared to be about the same as at 10 lb. Manufacturers advise the use of piston blowing engines for pressures exceeding 5 lb. Hixon<sup>61</sup> does not believe that the field of the blowing engine proper exists below 5 lb. Vezin<sup>62</sup> maintained several years ago that rotary pressure-blowers were not any cheaper than cylinder blowing engines with pressures of from 1 to 2 lb. on account of the back leak or slip. Notwithstanding the criticisms of specialists, rotary pressure blowers of unusual sizes are being built to meet the increasing demands, because they are believed to be cheaper. Thus a furnace<sup>63</sup> 42×140 in. to be driven under a pressure of 40 oz. has recently been provided with a No. 10 blower, to be run at 100 revolutions per minute, which with a displacement of 300 cu. ft. per revolution corresponds to 30,000 cu. ft. per minute. The force required to drive the blower approximates 400 H.P.

Channing<sup>64</sup> gives an example of a piston-blowing engine and a rotary pressure

blower recently erected to supply two copper blast furnaces. The engine of the Tennessee Copper Co. has two air tubes 57×42 in.; the steam cylinders, of the Corliss type, are 13 and 24 in. by 42 in. The blast pressure is 2.5 lb. per sq. in. The smelter of the Santa Fe Gold & Copper Mining Co. has recently installed a No. 8 blower directly coupled to a 14×32-in. Corliss engine. The blast pressure being 12 oz. to the sq. in.

*Utilization of Blast-furnace Slags.*—At the Chemical Works "Marienhütte," Langesheim, Lower Harz Mountains,<sup>66</sup> the lead blast-furnace slags, rich in zinc and baryta, are treated in the following way: the slag is pulverized in a ball mill, mixed with calcium chloride and melted down at about 1,200°C. under oxidizing conditions in a reverberatory furnace. The melted mass, when cold, is pulverized in the ball mill and leached with water. There results a solution of barium chloride nearly chemically pure and a residue of calcium sulphate with some silicates of zinc and iron. The residue, while still moist, is transferred into lead-pans and treated with sulphuric acid of 50°B.; it soon becomes hot, turns white and solidifies. It is now mixed with calcium chloride, pulverized in a ball mill, and heated to 500°C., chlorides of zinc and iron are formed, the iron chloride being decomposed ( $2\text{FeCl}_2 + 2\text{H}_2\text{O} + \text{O} = \text{Fe}_2\text{O}_3 + 4\text{HCl}$ ), the hydrochloric acid set free being used to prepare calcium chloride from limestone. The mixture is finally treated with water giving a solution of zinc chloride containing a little iron and a residue, consisting mainly of calcium sulphate and ferric oxide. This is ground, dried and sold as red paint.

*Dust-Catcher.*—Cavallier<sup>66</sup> constructed a wet dust-catcher which collects the dust from the iron blast furnace at Pont-à-Mousson, France. In 24 hours 350,000 cu. in. of air pass through the dust catcher and deposit about 630 kg. of flue-dust.

*Condensation of Flue-dust.*—E. Balbach, Jr., patented<sup>67</sup> a condenser for flue-dust and fumes. It has the form of a tower with vertical partition walls that force the gas-current to zigzag up and down through the tower; at right angles to these deflection walls are air-cooled divisions connected by pipes that the gases in their zigzag passages may give up their heat and allow the fumes to settle out.

*Briquetting Flue-dust and Fine Ores.*—The Chisholm, Boyd & White Co.<sup>68</sup> state that 50 of their roller- and plate-mould briquetting machines<sup>69</sup> were in operation in March, 1901, and that during an 18-months' run the cost of briquetting at one plant was 62.5c. per ton, which figure included repairs of plant, power, labor, bond and automatic carrying of briquettes to the furnace floor. The briquettes are 2.5 in. in diameter and 4 in. high. The machine has a capacity of 80 briquettes per minute and requires 35 H.P. for operating the press and the auxiliary machinery which slacks the lime, separates the milk of lime from uncalcined particles of limestone, pumps it into a mixer into which the material to be bricked is fed automatically, incorporates the lime and delivers the prepared mixture to the press. The combined output of the briquetting

<sup>67</sup> *Berg- und Huettewuennische Zeitung*, 1900, p. 565. <sup>68</sup> *Engineering and Mining Journal*, March 2, 1901.

<sup>69</sup> United States Patent No. 676,380, June 11, 1901.

<sup>69</sup> See Hofman, *Metallurgy*, Sixth Edition, p. 404.

plants installed by this company in the United States and foreign countries is about 3,000,000 tons annually. Among the well-known lead and copper smelting companies using the White machine are: American Smelting & Refining Co. (10); La Gran Fundicion Central Mexicana (3); Northport Mining & Smelting Co. (2); Mountain Copper Co. (3); and many others. In all about 50 plants are using these presses for briquetting various materials.

The Henry S. Mould briquetting plant<sup>70</sup> has made considerable progress since it was first built a few years ago. Among the numerous smelting plants using the White briquetting press, which is manufactured by this company are: American Smelting & Refining Co.; Bingham Consolidated Mining & Smelting Co.; Anaconda Copper Co.; Nichols Chemical Co.; Greene Consolidated Copper Co., at La Cananea, Mex.; Old Dominion Copper Mining & Smelting Co.; Backus & Johnson Co., Lima, Peru; Compañia Minera de Piñoles, Mapimi, Mex.; Mount Lyell Mining & Railroad Co., Tasmania, etc. The combined annual output of the briquetting plants using the White briquetting press amounts approximately to 1,000,000 tons of briquettes.

Briquetting machines have been patented by R. Schorr<sup>71</sup> and J. T. Davis.<sup>72</sup>

#### DESILVERIZATION OF BASE BULLION.

*Parkes Process.*—A. Schertel<sup>73</sup> furnishes an interesting analysis of a felt-like metallic scaly mass of a bright copper-color which was found imbedded near the tap-hole of a softening furnace, the hearth-material of which consisted of:

FIG. 1.—CUPELLATION FURNACE WITH WATER-COOLED HEARTH.

mixture of raw and burnt fire clay rammed down firmly. The scales, which could not be entirely freed from hearth-material, showed the following composition: Cu, 59.75%; Pb, 33.46%; Sb, 0.37%; Ni, 0.65%; Ag, 0.13% Au, 0.0235%; total metal, 94.3925%; clay, 5.6%. Calculating the percenta

<sup>70</sup> *Engineering and Mining Journal*, Nov. 30, 1901.

<sup>71</sup> United States Patent No. 667,254, Feb. 5, 1901.

<sup>72</sup> United States Patent No. 678,360, July 16, 1901.

<sup>73</sup> *Freiberger Jahrbuch*, 1900, 59, 1901.

he basis of metal alone, gives: Cu, 63.31%; Pb, 35.45%; Sb, 0.39%; 0.69%; Ag, 0.137%; Au, 0.025%. Now the base bullion, freed from cop-  
 cross in a liquation furnace, contains 0.06 to 0.10% Cu before it is charged  
 softening furnace, and this amount grows to 0.12 to 0.15% by the removal  
 he arsenic and antimony. That such small amounts should separate out  
 is remarkable. Traces of nickel and gold are seen to have been concentrated  
 he scaly product in a much more remarkable degree even than copper.

FIG. 2.—CUPELLEATION FURNACE. DETAILS OF HEARTH CONSTRUCTION.

**Electrolytic Refining.**—A. G. Betts<sup>74</sup> patented a process for the electrolytic  
 ing of base bullion in which lead fluosilicate,  $PbSiF_6$ , is said to be the  
 rolyte. This salt is claimed to be soluble in acid solution and to show a  
 conductivity, also no lead is said to be deposited on the anode as peroxide  
 it is used.

**Cupeellation.**—E. A. Weinberg<sup>75</sup> describes, as shown in Figs. 1, 2 and 3, a water-  
 d test for concentrating retort bullion. One peculiarity of the water jacket

<sup>74</sup> *Electrical World and Engineer*, 1901, p. 260.

<sup>75</sup> *Transactions of the Australasian Institute of Mining Engineers*, 1901, Vol. I., 167.

is that the inside is 0.375-in. copper plate and the outside 0.375-in. mild-steel plate, the breast is of brass. The author adopted this construction, as he had found that mild steel was soon corroded when the litharge, after having begun to eat into the filling, came in contact with it, while a copper test-ring had stood for over five years. The test, oval in shape, is 7.5 ft.  $\times$  5 ft. 5 in. inside. The filling is made of five parts of cement and one part of sand, the bottom and sides are made 4 in. thick. The test which is run into position on a truck and held in place by jack-screws, holds 4,265 lb. of metal when new, and as

FIG. 3.—CUPELLATION FURNACE. DETAILS OF CUPEL CONSTRUCTION.

much as 4,700 lb. when worn. Its life is three months when used for cupelling alone and two months when treating all sorts of drosses.

#### LEAD POISONING.

F. Blum<sup>76</sup> published in pamphlet form a summary of what has been found useful in combatting lead poisoning, supplementing it with his researches. Lead ores, the author says, ought not to be allowed to become dry before it is absolutely necessary; this is especially the case with carbonate ores which are more harmful than sulphides or sulphates. Sulphurous gases which are so common around

<sup>76</sup> *Untersuchungen ueber Bleivergiftungen und ihrer Verhuetung in Industriellen Betrieb, Frankfurt-a-Main, 1900.*

id plants treating sulphide ores are harmful. This is contrary to generally cepted ideas, but the author, by synthetical experiments, has shown this to be fact. In dusty places, nose and mouth are best protected by a sponge, by tton or some other respirator as long as this does not contain any valves. Men gaged in lead work ought to be watched to see whether lead is having a bad fect or not, as some men stand lead fumes and dusts for years, while hers feel the bad effects in weeks; the latter men ought, of course, give up lead-work at once. When a man has become leaded and is ap- rently well again, it is advisable to keep him at some other work for several eeks, for if he returns at once to his regular occupation, he is liable to be taken own in a very short time. Alcoholic beverages and acid foods are to be avoided, hile glutinous foods ought to be taken frequently.

At present, no remedy is known which will assist to rid the body of the lead at has got into it. Potassium iodide, which has always been recommended, as been found by Dr. Blum to have no effect whatever. Of course cleanliness ad good ventilation are the principal means of preventing men from becoming aded. A supplement contains the experiments and opinions of W. H. Hutch- ings, manager of the lead works of Cookson & Co., Newcastle-upon-Tyne, which ve a daily capacity of 200 tons white lead and 50 tons red lead. In 1898 ere was only a single case of lead poisoning, and a light one at that; in 1899 ere were five, and in the first six months of 1900, none at all.

Hutchings finds that lead sulphide and sulphate are practically harmless, id oxide is poisonous and carbonate exceedingly so. He believes, contrary to e opinion generally held, that lead enters the human body only through mouth d nose and not through the pores of the skin. As to protective measures the st of ventilation and cleanliness of floors are essential. The only remedy that s so far proved somewhat efficacious is the use of lozenges made of sulphur, gar and peppermint, containing 0.5 grain of sodium sulphide; the sulphur d alkaline sulphide converting the lead into harmless sulphide.

## MAGNESITE.

THE production of magnesite in the United States continues to be derived solely from California, and in 1901 the output amounted to 13,172 short tons, valued at \$43,057, as compared with 2,708 short tons, valued at \$11,832 in 1900. The reported production in 1901 was comprised of 3,112 short tons of crude magnesite and 4,726 short tons of calcined magnesite, which latter is equivalent to 10,060 short tons of the crude product, making a total of 13,172 short tons.

### PRODUCTION OF MAGNESITE IN CALIFORNIA.

| Year.     | Crude.      |                |          | Calcined.   |                 | Crude Equivalent of Calcined Short Tons. | Total Crude. |         |
|-----------|-------------|----------------|----------|-------------|-----------------|------------------------------------------|--------------|---------|
|           | Short Tons. | Value at Mine. | Per Ton. | Short Tons. | Value at Works. |                                          | Short Tons.  | Value.  |
| 1897..... | 379         | \$1,516        | \$4.00   | 764         | \$10,700        | 1,598                                    | 1,907        | \$7,688 |
| 1898..... | 200         | 800            | 4.00     | 1,013       | 14,200          | 2,155                                    | 2,355        | 9,499   |
| 1899..... | 400         | 1,300          | 3.00     | 800         | 12,300          | 1,600                                    | 2,000        | 7,900   |
| 1900..... | 469         | 1,876          | 4.00     | 1,013       | 15,900          | 2,239                                    | 2,708        | 11,832  |
| 1901..... | 3,112       | 16,725         | 5.37     | 4,726       | 36,332          | 10,060                                   | 13,172       | 43,057  |

The very considerable increase in the production of magnesite in the United States during 1901 resulted from its extensive use as a refractory lining for open-hearth furnaces and converters in the steel industry, for lining rotary kilns used in the manufacture of Portland cement, and as a non-conducting covering for boilers, steam pipes, etc., to prevent the loss of heat. There is also a considerable quantity utilized in the manufacture of carbon dioxide gas for carbonating beverages. The carbon dioxide gas is produced from magnesite by treatment with sulphuric acid or by the application of heat alone; in the former case magnesium sulphate ( $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ ) or Epsom salts is made as a by-product, the production of which during 1900 is estimated at 8,000,000 lb. Magnesite bricks for the refractory lining of furnaces are made in this country by the Fayette Manufacturing Co., at Layton, Pa., and by the Harbison & Walker Co., of Pittsburg, Pa. The latter company is equipped to manufacture 3,000,000 brick annually and has furnished the following analyses of its products: Grecian magnesite brick:  $\text{CO}_2$  0.14%,  $\text{Al}_2\text{O}_3$  0.686%,  $\text{SiO}_2$  3.2%,  $\text{Fe}_2\text{O}_3$  0.3%,  $\text{CaO}$  1.9%, and  $\text{MgO}$  93.876%. Styfian magnesite brick:  $\text{CO}_2$  0.04%,  $\text{Al}_2\text{O}_3$  0.98%,  $\text{SiO}_2$  3.4%,  $\text{Fe}_2\text{O}_3$  5.1%,  $\text{CaO}$  2.8%, and  $\text{MgO}$  87.8%.

The importation of crude and calcined magnesite during 1901 was 33,461 short tons, as compared with 28,821 short tons in 1900, the supply being derived

mainly from Greece and Styria. No statistics are available for the importation of magnesite bricks, which is of considerable importance. The greater part of the consumption of magnesite in the United States is derived from foreign sources.

*Austria.*—The plant of the Veitscher Magnesitwerke Act.-Ges., at Veitsch, Styria, employs 1,500 men and has a capacity of producing 100,000 tons of finished product, which embraces raw, burnt and sintered magnesite in large and small lumps and finely ground, mortar, burned bricks and other shapes for iron and steel furnaces, cement kilns, etc., pipes, crucibles, tuyeres for basic Bessemer converters, etc.

The following analyses of calcined magnesite and magnesite bricks have been furnished by Paul Mansfeld, of Budapest, Hungary:—

|                                | MgO.  | CO <sub>2</sub> . | Fe <sub>2</sub> O <sub>3</sub> . | SiO <sub>2</sub> . | Al <sub>2</sub> O <sub>3</sub> . | CaO.  | Loss. | P <sub>2</sub> O <sub>5</sub> . | Undetermined. |
|--------------------------------|-------|-------------------|----------------------------------|--------------------|----------------------------------|-------|-------|---------------------------------|---------------|
|                                | %     | %                 | %                                | %                  | %                                | %     | %     | %                               | %             |

| Calcined magnesite.....        | 91.50 | .....             | 6.90                             | .....              | .....                            | ..... | ..... | .....                           | .....         |
| Mansfeld magnesite bricks..... | 91.62 | .....             | 6.05                             | 0.35               | .....                            | 2.10  | ..... | .....                           | .....         |
| Styrian magnesite bricks.....  | 83.00 | .....             | 7.60                             | 3.45               | 1.30                             | 3.90  | 0.20  | 0.08                            | 0.47          |

A. Vesterberg has made an elaborate study on the effect of heat on magnesite and dolomite which shows that the magnesium carbonate is present in the latter as a double salt of magnesium and calcium (Mg.Ca)CO<sub>3</sub>.

*Greece.*—Two companies, one English and the other Greek, are now operating the magnesite mines of Eubœa, the Greek company shipping both the raw and calcined magnesite from the small seaport of Katunia. Until recently primitive wood-fired kilns were employed for calcining the ore, which required a large quantity of fuel; recently, however, modern shaft calciners have been constructed and a local lignite is used to advantage both for cost and working. Magnesite when completely calcined falls to powder when moved and chokes the lower or cooling portion of the ordinary kiln, preventing the access of air and heated gases necessary for calcination. The modern furnace is especially constructed to overcome this result. From 16 to 20% of lignite is required for the complete calcination of the magnesite. Small pieces are best calcined in a double-hearth reverberatory furnace with the flame in direct contact with the freshly charged magnesite on the upper hearth, the operation being completed on the lower and hotter hearth. Pure magnesite from Eubœa is highly refractory and sinters only at a very high temperature, and for the manufacture of magnesite bricks it is necessary to add a suitable binding material. The Greek company, at its works at Mantudi, uses a small proportion of serpentine in its mixture, and produces a very hard and dense brick by burning at a temperature of 1,400°C. in a regenerative furnace of the Siemens type. Their product is consumed in metallurgical works of the United States and elsewhere.

*Russia.*—An analysis of a sample of magnesite from a large deposit recently discovered in the Department of Ufa, Southern Urals, gave MgO 46%, CaO 0.85%, Fe<sub>2</sub>O<sub>3</sub> and Al<sub>2</sub>O<sub>3</sub> 1.62%, SiO<sub>2</sub> 0.3%, and CO<sub>2</sub> 51.23%; total 100%. This magnesite is to be used for the manufacture of magnesite bricks at the recently erected works near Zlatoust.

## MANGANESE.

THE production of manganese ores of all grades in the United States during 1901 is given in the subjoined table, which does not include the manganiferous iron ores of Colorado and other Western States consumed as a flux in silver-lead smelting, although account is taken of that portion sold to steel makers for the manufacture of ferromanganese and spiegeleisen. The average manganese content of the ores from the different States is shown in the second table. For details of the American consumption and supply, reference may be made to the article by Alfred A. Wheeler in THE MINERAL INDUSTRY, Vol. VIII. The composition and occurrence of the ores of manganese have been fully set forth in the preceding volumes.

The subjoined table shows the relative production for the years 1897 to 1901 of the high-grade ore from Arkansas, California, Georgia, Tennessee and Virginia; of Colorado ores used for steel making purposes; of the low-grade ores from Michigan and Wisconsin, and of the manganiferous residuum from the zinc oxide works of New Jersey and Pennsylvania.

STATISTICS OF MANGANESE ORE IN THE UNITED STATES. (IN TONS OF 2,240 LB.)

(a) Not including 2,500 tons from Utah and small quantities aggregating 65 tons from Alabama, Missouri and North Carolina, of which the manganese content was not reported.

The price of manganese ore is determined by the Illinois Steel Co., according to the following schedule which is based on ores containing not more than 8%  $\text{SiO}_2$  and 0.1% P. Deductions are made of 15c. per ton for each 1% of  $\text{SiO}_2$  in excess of 8%, and of 1c. per unit of manganese for each 0.02% P in excess of 0.1%. Ores delivered at the works of the company, South Chicago, Ill. Settlements are based on analysis of samples dried at  $212^\circ\text{F}$ .; the percentage of moisture in the samples as taken being deducted from the weight.

| Tenor in Mn. | Price per Unit. |      | Tenor in Mn. | Price per Unit. |      |
|--------------|-----------------|------|--------------|-----------------|------|
| %            | Fe.             | Mn.  | %            | Fe.             | Mn.  |
| Over 40      | 6c.             | 28c. | 37 to 40     | 5c.             | 24c. |
| 46 to 40     | 6c.             | 27c. | 34 to 37     | 5c.             | 23c. |
| 43 to 46     | 5c.             | 26c. | 31 to 34     | 4c.             | 22c. |
| 40 to 43     | 5c.             | 25c. | 28 to 31     | 4c.             | 21c. |

Schedules of prices offered by the Carnegie Steel Co. differed but slightly in detail from the above, being about 1c. per unit lower for manganese.

The imports of manganese iron ore during 1901 were 165,722 long tons, valued at \$1,486,573, as compared with 256,252 long tons, valued at \$2,042,361. This large increase is attributable to the low price of foreign spiegeleisen and ferromanganese, large quantities of which were used by the steel makers in preference to the purchase of manganese ores and the manufacture of the products themselves.

Metallic manganese is now being manufactured at Essen, Germany, by the Goldschmidt process of aluminum reduction. Its relatively high cost, as compared with ferromanganese, however (about 10 to 1), limits its use mainly for the manufacture of copper alloys. The pure metal oxidizes very slowly in the air and alloys readily with other metals. Manganese-iron-titanium alloys have been made containing as high as 40% Ti, but these are so refractory that an alloy of from 20 to 25% Ti is generally used. The presence of titanium in iron or steel even in quantity not exceeding 0.2% produces a very tough, fibrous structure to the metal, and as this element will unite much more readily with manganese than with iron, a manganese-titanium alloy containing from 30 to 35% Ti has been used with good results in place of ferrotitanium. Furthermore, the manganese alloy dissolves more readily in the molten iron than the iron alloy.

*Colorado.*—According to the report of the Hon. Harry A. Lee, the production of mangiferous iron ores in Colorado during 1901 was derived from Lake County solely, and amounted to 68,500 long tons of an average composition of from 28 to 30% Mn, 22 to 24% Fe, 3 to 4%  $\text{SiO}_2$ , 0.035 to 0.05% P and 4 to 10%  $\text{H}_2\text{O}$ . About 65% of the output was shipped to the Illinois Steel Co., Chicago, Ill., and 35% was used in Colorado for the manufacture of ferromanganese and spiegeleisen. A large quantity of mangiferous iron ores was consumed during the year as a flux by the silver-lead smelters, which is not included in the statistics of production.

*Georgia.*—(By T. L. Watson.)—The manganese ore deposits of Georgia have been continuously worked for many years, and during the early development the ore was marketed chiefly in England; at present, however, the entire output is

consumed in the United States, where it is used principally for the manufacture of ferromanganese and spiegeleisen, and to a less extent in bleaching purposes.

Of the manganese oxides which occur in the deposits, pyrolusite and psilomelane greatly predominate, with some manganite and braunite, and in places considerable wad (the earthy oxide). These oxides usually occur admixed in varying proportions, and cannot always be separated. The distribution of the workable ores is limited chiefly to Bartow, Floyd and Polk counties. In Bartow County the Cartersville district has furnished almost the entire manganese output of the State. In 1901 considerable manganese was mined and shipped from the Cave Spring district in Floyd and Polk counties, near the Alabama State line. A very promising area has more recently been opened to the east of Rome, in Floyd County, near Lindale. Small amounts of the ore have been mined from time to time at several other places in the more northwestern portion of the State. No workable deposits of manganese have as yet been opened beyond the limits of the Paleozoic group, although limited occurrences of the manganese oxide are known at many points in the Crystalline area.

The manganese ore in the workable areas occurs chiefly as lumps and masses, mostly in the form of irregular pockets, small veins and stringers, and rarely as true beds. The ore is embedded in the heavy mantle of residual decay derived from the Knox dolomite, Beaver limestone and Weisner quartzite (Chilhowee sandstone of Safford). The residuary mantle is composed of light gray, yellow and red clays, through which the ore is irregularly distributed. In the Cartersville district the nodules or concretions are largely, partially, or entirely crystalline and usually display the concentric or layered structure to some degree. The Georgia manganese deposits are secondary accumulations concentrated in the residual clays by chemical and physical processes. The ore is mined entirely by open cut, shaft and tunnel work, and on account of its limitation to the residual clays, no heavy or expensive machinery is required. The workings are usually confined to the tops and slopes of the limestone and quartzite ridges, less often to the valley bottoms. The ore is rarely free from some included or admixed quartz and sand, which are often present in sufficient amount to necessitate crushing the ore before washing and jigging. The adhering clay is freed from the ore by washing in a log washer similar to those used in cleansing brown iron ores and ocher.

The manganese deposits are intimately associated with extensive deposits of brown iron ore and some gray specular hematite, and in the Cartersville district, with the deposits of yellow ocher. The proportion of clay to ore is usually larger in case of the manganese than in the closely associated brown iron ores.

*Virginia.*—The Crimora Manganese Co. continued to exploit the deposit formerly worked by the Carnegie Steel Co., and apparently has successfully adapted the hydraulic process to the peculiar conditions prevailing in the mine. The ore is found in irregular detached masses of variable size scattered through a stiff clay which occupies a basin 0.75×1.5 mile, and 250 ft. in extreme depth. Formerly the ore was extracted by shafts and drifts, a method that was both expensive and wasteful. As subsequently shown, the development frequently

iled to locate masses of ore that were in close proximity to the workings, though they might have been discovered without much difficulty by hand drilling. By the hydraulic process as used there, the top layer of gravel and alluvium first removed in cars and the clay bank is then washed down under a powerful pad of water. The ore being separated from the clay, is shoveled on wheelbarrows and carried to the mill located at the edge of the pit, where it passes through a crusher and washer and is then screened; all material over 0.5 in. in size is passed to a belt sorter and the undersize to jigs.

(a) From official statistics, except for the United States and Colombia, for which direct reports have been received from the producers. (b) Includes Herzegovina. (c) Statistics not yet published. (d) Export returns. (e) Shipments as stated in British Diplomatic and Consular Reports, except for 1899, which are estimated.

## THE PRODUCTION OF MANGANESE ORE IN FOREIGN COUNTRIES.

**Belgium.**—This country produces some mangiferous iron ore, but, strictly speaking, no manganese ore. The output varied from a minimum of 700 tons in 1880, to a maximum of 28,000 tons in 1897, falling to 11,000 tons in 1900.

**Brazil.**—The production of manganese ore in Brazil began in 1895 and has continued in increasing growth until 1900, in which year the shipments of ore amounted to 127,000 metric tons. During 1901 however the shipments decreased to 96,000 metric tons. In THE MINERAL INDUSTRY, Vol. IX., is an abstract of the comprehensive paper on "Manganese Ore in Brazil," by Mr. H. K. Scott, which appeared in the *Journal of the Iron and Steel Institute*, Vol. I., 1900. This paper has been supplemented by a description of the manganese ore deposits at Queluz, Lafayette district, by Mr. Orville A. Derby, in the *American Journal of Science*, July, 1901, from which the following abstract has been made:

"Queluz District.—In this district, the ore bodies occur in association with granite and gneissic rocks, the calcareous and ferruginous beds that accompany the ore in the other district being completely absent. The mining and prospecting operations thus far effected have been limited to a zone 10 to 20 km. wide on each side of the railroad. In this zone the outcrops of ore are so numerous and large as to indicate an extremely extensive mineralization of an area apparently larger than at present recognized. The existing maps of the region are so defective that no positive correlation of the different outcrops can be made, but there are strong indications of the existence of at least three distinct ore belts."

Although the export duty on manganese ores was reduced to 4% and import duties on mining appliances removed to a great extent, it has been estimated that the product cannot be profitably mined at an exchange of over 12d. per milreis. Several of the smaller mines have suspended operations, although the exports to the United States, United Kingdom and Belgium during the first eight months of 1901 amounted to 34,000 long tons. The shipments during 1900 were 88,127 tons, valued at £151,000, the rate of exchange being taken at 9·5d. to the milreis.

*Canada.*—The production of manganese ore, principally obtained from New Brunswick and Nova Scotia, has ranged from a yearly minimum of 15 tons to a maximum of 1,789 tons. Since 1897 (with the exception of 1899, when some of the bog or wad manganese ores of New Brunswick were manufactured into spiegeleisen), the total amount mined annually has not reached 100 tons. The establishment of the large steel plant of the Dominion Iron & Steel Co., at Sidney, Cape Breton, will doubtless encourage the development of the Canadian manganese ore deposits. The exports of manganese ore during 1901 amounted to 440 short tons, valued at \$4,820.

*Chile.*—Manganese ores are shipped from the ports of Coquimbo and Carrisal, and occasionally small amounts from Santiago. The mines shipping from the port of Coquimbo are on the plain of Corral Quemada, about 60 miles distant. The analyses of these ores show Mn, 50 to 51·65%; insoluble, 8·4 to 9·63%;  $\text{SiO}_2$ , 4·73 to 5·95%; P and Cu, traces; CaO, 4·9 to 8·9%, and moisture, 0·15 to 0·27%. A railroad about 50 miles in length has been built from Carrisal to the manganese mines at the foot of the Ten-Mile mountains, where a number of lodes, averaging from 4 to 5 m. wide are reported. Analyses of 12 samples of ores from this district, indicate Mn, 40·26 to 57·18%;  $\text{SiO}_2$ , 8·40 to 11·77%, and P, 0·079 to 0·09%. The small quantity of manganese ore exported from Santiago comes from Aculeo, about 32 miles south of Santiago. The yield is about 50% Mn. Manganese ores have also been found at other points, but owing to the lack of railway communication or the poor quality of the ore, the deposits are of no present commercial value.

*Colombia.*—The manganese ore deposits at present worked are on the Isthmus of Panama, near the Caribbean Sea, about 45 miles N.E. of Aspinwall. The Caribbean Manganese Co., an American concern, is the most important producer in Colombia, and the bulk of ore mined is sent to the United States. In recent years the annual production has ranged from about 8,000 to 10,000 long tons, but in 1901 only 700 tons were shipped.

*Cuba.*—The mines of the Ponopo Mining & Transportation Co., the Standard Manganese & Mining Co., and the Sierra Maestra Mining Co. are located in the Province of Santiago de Cuba, about 23 miles from the town of the same name, on the tops or flanks of small hills that branch from the Sierra Maestra Mountains. The rocks in the neighborhood of the deposits are much decomposed, with the exception of some boulders of porphyry and the jasper which are associated with the ore, and it is asserted that this and the thick vegetation, make it difficult to determine the exact geological formation. At the Ponopo mines it is claimed that manganese may have been derived from one of the igneous rocks, in which it is often present in the form of silicate. This having been chemically decomposed

when the rocks were disintegrated by the action of atmospheric agencies, the manganese was carried in solution to the surface waters, and aided by favorable conditions, was deposited in the form of oxide. As the deposition of the ore was governed by local conditions the extent and continuity of the deposits have to be investigated in each particular case. The ore is found in pockets of greater or less extent, embedded in clay, which has resulted from the decomposition of the original enclosing rock. This clay, in places, assumes various shades of color; red, white and yellow, due to the different stages of oxidation of the iron and manganese contained. The ore is also found associated with red or yellow jasper.

*France.*—The greater portion of the manganese ore obtained in France is of the carbonate variety from the mines of Las Cabesses (Ariege), which produces annually about 5,000 tons of ore. The tenor of manganese in the ore being increased by calcination from 40 to 45% raw, to 50 to 56% in shipped ore. Smaller amounts are contributed by the mines Romaneche, the Grande Filon (Sàone and Loire), where manganese dioxide is obtained.

*Germany.*—The greater portion of the home supply is furnished by Prussia, which contributes 98% of the total in the form of manganiferous iron ore, the value ranging from \$3 to \$7 per ton.

*Greece.*—The French Government is reported to be carrying on manganese ore mining at Cape Vani, on the northwestern part of the Island of Minos. The ore is claimed to be the dioxide occurring in a basin of Tertiary sediments which are penetrated by trachytic dikes. The ore is mined by open cuts and shafts, and when sorted, contains from 32 to 41%  $MnO_2$ . The output ranges from 10,000 to 15,000 tons per year. From 150,000 to 400,000 tons of manganiferous iron ore is annually produced in Greece.

*India.*—Manganese deposits exist along the East Coast Railway in Vizayanagaram State, Vizagapatam district, and are found in the Chipurupalle taluq of that State. These are chiefly "pockets" close to the surface and reported to be of good quality. Manganese ores are also found in the trap rocks of Belgaum, Dhawar, and Ratnagiri districts, in the Bombay Presidency, and Jhabua, in Central India. An extensive bed of ore, reported to be several miles in extent, exists in Lower Burma. Three localities are specified, viz.: the bank of the Thugo stream, the bank of the Thriabuen, and the great Tenasserim river. The ores are stated to consist of black and gray oxides and wad. The greater portion of ore mined comes from the Madras Presidency, which has shown a constantly increased output from 1,000 tons in 1892 to over 130,000 tons in 1900. Manganese ore is now being mined at Nagpore, and exported from Bombay. This production adds considerably to the quantity exported, which has heretofore come from the mines of Vizagapatam. Indications of manganese deposits have been reported in the Bhandara and Balaghat districts, and explorations are being made.

*Italy.*—Deposits of both manganese and manganiferous ores occur in Italy, the latter being worked in an intermittent manner, in some instances mining having been interrupted for years. The present annual production of manganese ore is from 4,000 to 5,000 tons, valued at about \$5 per ton. The amount of manganiferous iron ore produced has varied greatly, in some years none being mined, while in others nearly 30,000 tons have been mined.

*Japan.*—Deposits of manganese ore occur in Japan, but it is unlikely that they will ever become a prominent source of supply. A small portion of the product is used in the steel works lately put in operation in that empire, the balance of the ore is exported, amounting in late years to from 6,000 to 9,000 tons, a large decrease from the export of 20,000 tons in 1896, attributable to imperfect preparation.

*Java.*—Small amounts of manganese ore are produced in the Regencies of Pengasih and Nanggolan. In some years no ore is mined, while in others over 500 tons have been exported.

*Russia.*—Fully one-half of the world's supply of manganese ore is derived from the Russian Empire, the bulk coming from the Caucasus district, which has been fully described by Mr. Frank Drake in previous volumes of THE MINERAL INDUSTRY. Practically all of the manganese ore known in the market as Caucasian ores comes from Chiaturi, although deposits exist also at other localities, viz.: Kutis, near Chiaturi; near the Choruk river, and in Erivan and Tiflis.

The manganese ore deposits as opened in seven of the hills near Chiaturi, in a brown sandstone of Miocene age, have an average thickness of between 6 and 7 ft. and are free from extreme variations. The deposit has a distinctly stratified structure and is composed largely of pyrolusite, but other manganese oxides also occur. It is quite certain that an area of more than 22 sq. miles of the present surface is underlaid by ore available for mining. With proper sorting no ore from Chiaturi should carry less than 51% Mn. The phosphorus in the ore shipped at present averages about 0.16% and silica not above 8%. The figures given above refer to ore dried at 212°F.

An additional source of supply is the Nicopol district, the initial shipments being made in 1897. The average analyses showed: Mn 46%,  $\text{SiO}_2$  12.5%, and P 0.25%. Messrs. Leech, Harrison and Forwood, of London, give the average analyses of Chiaturi ore, when dried at 212°F. as: Mn 51%, P 0.15%,  $\text{SiO}_2$  7.5 to 8.5%, and Fe 1%. The manganese ores of the Nicopol district are described in detail in the special article by Mr. Frank Drake, given later in the following pages of this section.

The mines are usually owned by natives, who hold parcels of ground varying in size from 0.5 acre to 50 acres. Some of the proprietors mine the ore from their own land while others lease the mining right and receive a royalty therefor. The railroad from the mines to the harbor is owned by the Government, which makes exorbitant charges for shipment from Chiaturi to Sharopon, a distance of about 25 miles. The exports of manganese ore from Batoum and Poti during 1900 were 373,202 and 52,917 long tons, respectively, which was a considerable decrease from the exports during 1899.

*Spain.*—The greater portion of the manganese ores produced in Spain is of the carbonate and silicate varieties, from the Province of Huelva. Mr. Carlos Sundheim states that one-half of the output is silicate, averaging 33% Mn and from 30 to 37%  $\text{SiO}_2$ . The shipped ore is classified as yielding from 40 to 47% Mn, with 16%  $\text{SiO}_2$ ; from 36 to 39% Mn, with 16%  $\text{SiO}_2$ ; 34% Mn, with 16%  $\text{SiO}_2$ , and 30% Mn, with no guarantee as to silica. The ore is exported principally to Belgium and Luxemburg, where it is stated to be mixed with the

minous minette ores of Luxemburg for smelting. A small amount of manganese oxide, usually from 200 to 300 tons, is obtained from the provinces of Huesca and Teruel, but these localities will not be important producers until railroads are built to the mines. The total production of manganese ore in Spain ranged from about 400 tons in 1894, to 136,500 tons in 1899, falling to about 13,000 long tons in 1901. The exports of manganese ore during 1901, as reported by the *Revista Minera*, were 91,672 metric tons, as compared with 129,916 metric tons in 1900.

*Sweden.*—Sweden has been a constant producer of small amounts of manganese ore, all of which comes from Wermlands and Jonkopings. In recent years from 2,000 to 2,700 tons have been mined, but in 1890 the total production amounted to more than 10,000 tons.

#### THE NICOPOL MANGANESE DISTRICT IN SOUTHERN RUSSIA.

BY FRANK DRAKE.

NICOPOL is a town in the Government of Ekaterinoslav, on the river Dneiper, about 190 miles above Odessa. Being the point from which shipments of ore

FIG 1.

At their departure for the outer world, Nicopol has given its name to the neighboring manganese district as well as to the ore, although the deposits lie at a considerable distance from the town.

The accompanying map, Fig. 1, shows the region surrounding Nicopol, with the localities at which manganese ore has been mined or discovered, and indicates in a general way, the location and extent of the district.

The first discovery of ore was made on the Pocroffsky estate of the Grand Duke Michael Nicholovitch, in 1885, or previously. Preliminary explorations were made in that year, and mining commenced in 1886, the workings then opened becoming known as the Pocroffsky mines. At present the following mines are in operation:

1. The Pocroffsky mines, comprising part of the Pocroffsky estate, and also including territory leased from the neighboring D'Usso estate; operated by the Nicopol-Marioopol Mining & Metallurgical Co. Up to the end of 1891 these were the only mines in the district, the others mentioned below having since been gradually opened.

2. The Llwoff mines, on the D'Usso estate; operated by the engineer Llwoff.

3. The Briansk mines, on the D'Usso estate; operated by the Briansk Co.

4. The Gorodistcheffsky mines (also called Dneiprofsky mines), 30 *versts* southeast from the three above mentioned; operated by the Dneiprofsky Co.

5. The mines of the Pyrolusite Co.

Of these mines the first three are grouped along a small stream, known as Salt river (so called on account of the taste of its waters), while the others are near the village of Nicolaiovka, about 20 miles southeast from this locality.

The mines near Salt river are leased by their operators at royalties equivalent usually, to from 60 to 90c. per ton of ore shipped.

So far as is known, the Pocroffsky mines only, have exported ore; a considerable proportion of their total product, however, is used at the steel works at Marioopol, on the sea of Azov, or sold to Russian consumers. The Briansk Co. and the Dneiprofsky Co. use their entire product at their steel works, near Ekaterinoslav, while the product of the Llwoff mines is taken by the Briansk Co. Thus, nearly the whole product of the Nicopol district is used in Russia.

The production of the district (in long tons) has been as follows:—

|           |              |           |                  |           |              |
|-----------|--------------|-----------|------------------|-----------|--------------|
| 1886..... | 4,082 tons.  | 1891..... | 16,666 tons.     | 1896..... | 44,984 tons. |
| 1887..... | 3,551 tons.  | 1892..... | 23,961 tons.     | 1897..... | 55,996 tons. |
| 1888..... | 5,508 tons.  | 1893..... | (a) 76,450 tons. | 1898..... | 58,717 tons. |
| 1889..... | 8,517 tons.  | 1894..... | (a) 57,463 tons. | 1899..... | 95,400 tons. |
| 1890..... | 10,645 tons. | 1895..... | 86,981 tons.     | 1900..... | 87,223 tons. |

(a) Partly unassorted ore.

In 1901 the yield is said to have fallen off considerably, owing to the failure of a number of metallurgical enterprises in the south of Russia.

*Topography.*—The Nicopol district is part of the great steppe region of southern Russia, and its topography is of a prairie-like character with gentle undulations and an occasional marked eminence or depression. Except in some cases along permanent water courses, it is entirely treeless. It is an agricultural rather than a mining country and a large proportion of the land is utilized for farming purposes.

*The Ore Deposit.*<sup>1</sup>—In the district south of the Salt river, the manganese ore is found in a horizontally bedded deposit, usually about 3·5 ft. thick; in a few places the thickness shrinks to about 1 ft., while in others it increases to 6 ft.

<sup>1</sup> My personal familiarity with the Nicopol district is confined to the mines near Salt river, particularly the Pocroffsky mines, so that statements regarding the ore deposit and methods of working apply to the Pocroffsky and neighboring mines, rather than to the mines near Nicolaiovka. Access to the latter was denied me as well as information concerning them, and statements regarding their working are merely those current in the neighborhood.

the bed lies between strata of clay of similar appearance but of different geological ages, the overlying clay being of Miocene age, while the ore deposit itself and the underlying clay are Oligocene. The deposit consists mainly of a somewhat impure pyrolusite, intermixed to a greater or less extent with sandy, calcareous and argillaceous material, the proportion of the foreign matter varying considerably in different parts of the bed. The ore deposit is almost entirely lacking in the distinctly stratified structure that characterizes the similar manganese deposit of Chiaturi, in the Caucasus. The Nicopol ore occurs in massive form, and in some places is quite hard, while in others it is very soft. The harder parts are usually more or less porous and honeycombed, the cavities being generally filled entirely or partly with sandy or clayey matter. The texture of even the harder parts of the deposit permits the ore to be mined entirely by a pick without the use of explosives.

The workings near Nicolaiovka are said to be in a deposit having similar characteristics to the deposit at Salt river, and as manganese ore has been found at Kutumliksky, between Nicolaiovka and Salt river, it is possible that the workings are on the same bed. It may also be worth mentioning that a horizontal bed of manganese ore occurs near Krevoi-Rog, a village about 40 miles northwest from the Pocroffsky mines, and in line with them and Nicolaiovka. It would perhaps be an unwarrantable suggestion that the ore bed worked at Salt river is identical with that at Krevoi-Rog, but the facts as they exist are at least suggestive of very extensive manganese deposits in this part of Russia. The ores of this region are high in phosphorus and, in some localities, comparatively low in manganese, but as variations in the latter are characteristic of these, as well as of the Caucasian manganese deposits, it may be possible that there are localities within the manganese-bearing area containing ores of a grade desirable for metallurgical purposes.

*Chemical and Physical Characteristics of the Ore.*—The chemical characteristics of the crude ore in the vicinity of Salt river are indicated by the following partial analyses:—

|               | Moisture. | Silica. | Metallic Manganese. | Phosphorus. |
|---------------|-----------|---------|---------------------|-------------|
| Sample 1..... | 5.40      | 27.60   | 30.60               | 0.24        |
| Sample 2..... | 5.70      | 27.00   | 29.58               | 0.28        |
| Sample 3..... | 3.05      | 27.70   | 34.63               | 0.25        |

At Nicolaiovka the crude ore is said to carry about 30% Mn.

The grade of the shipping ore produced at the Salt river mines by separating the gangue from the crude ore by hand picking, is shown by the following analyses of samples representing two large shipments from Pocroffsky mines: Sample 1: Moisture, 8.05%;  $\text{MnO}_2$ , 66.78% (42.21% Mn);  $\text{SiO}_2$ , 13.95%;  $\text{Fe}_2\text{O}_3$ , 2.49%;  $\text{Al}_2\text{O}_3$ , 2.95%;  $\text{MgO}$ , 2.38%;  $\text{P}_2\text{O}_5$ , 0.42%; C, 1.64%;  $\text{SO}_3$ , 9.95%; total, 99.61%. Sample 2: Moisture, 3.40%;  $\text{MnO}_2$ , 73.89% (46.71% Mn);  $\text{SiO}_2$ , 13.62%;  $\text{Fe}_2\text{O}_3$ , 2.68%;  $\text{Al}_2\text{O}_3$ , 2.33%;  $\text{MgO}$ , 2.17%;  $\text{P}_2\text{O}_5$ , 0.45%; C, 1.41%;  $\text{SO}_3$ , 0.91%; total, 100.86%. At the Dneiprofsky mines the washed crude ore yields two grades of shipping product, one containing about 50% Mn, and the other about 40% Mn.

The physical characteristics of the Nicopol ore are favorable to its commercial value, as it contains a fair proportion of lumps, usually of a porous nature; while, for the most part, both the lumps and the smaller pieces are at least moderately hard, so that comparatively little fines are produced by handling.

*Labor and Wages.*—The mines in the Nicopol district are dependent for labor to operate them, largely on the neighboring peasantry, reinforced to a greater or less extent by the migratory bands of peasants which form so striking a feature of Russian peasant-life. The underground laborers are the most stable, and, while coming originally from the local peasantry, they have abandoned agricultural labor and form a fairly permanent, though limited, mining population. The labor employed in screening and sorting the ore and for general surface work, however, is composed almost entirely of migratory bands, and is not only uncertain as regards supply but also of an unstable character. This class of labor is composed of peasants who, on account of insufficiency of employment, have left their native villages for parts of the country where work is obtainable. Among them is a considerable proportion of women, who are largely employed at the mines for sorting ore.

Agriculture being the dominant industry of this region, its requirements and convenience have molded custom in matters pertaining to labor employment. Thus there has arisen a practice of employing labor an entire season (summer or winter) for a lump sum, and from this has resulted the custom of the migratory peasants of leaving their employment and returning to their villages for a longer or shorter time at the end of each season's work. Through the practice of generations, this custom has become so fixed that it is difficult to persuade the peasants to forego these visits to their homes, consequently the mine operators are compelled to submit to the inconvenience of having practically their entire force of ore-sorters desert for a more or less uncertain period each year.

There is a large demand from the mine operators for men, horses and wagons to transport the ore from the mines to the Dneiper, and this work is performed by the local peasantry in seasons when there is no agricultural work. The supply of labor for transportation is thus uncertain and quite as unsatisfactory as that for sorting of the ore. The wages earned by miners in the Nicopol district are from 60 to 65c. per day, lodging, fuel and water being furnished in addition. Mechanics receive about the same wages as miners, except when employed by the season, or by the year, in which case their wages are lower. For ore sorters working by the day, wages are from 30 to 50c. per day for men, and from 25 to 35c. for women, lodging, fuel and water being furnished as in the case of the miners. Men employed by the season for sorting ore, and for general labor, receive about 32c. per day for the summer season, and about 15c. for the winter season, while women employed by the season receive about 20c. per day for the summer and about 12c. for the winter. All laborers employed by the season, however, receive in addition lodging, food, fuel and water, which, excepting lodging, costs the employers about 8c. per day for each person. The wages for peasants engaged in transporting the ore are from 70c. to \$1.25 per day, for man, a wagon and two horses. All regularly employed laborers receive free med-

al attendance, and in some cases a hospital, school and church are maintained by the mine operators.

The hours of labor for miners and underground laborers are 10 per day, but conforming to the custom of the agricultural laborers of the region all surface laborers, excepting a few whose work obliges them to conform to the hours of the miners, work from sunrise to sunset, summer and winter, with intermissions of one hour for breakfast, one hour at noon, and one-half hour about 3 or 4 o'clock in the afternoon, for tea. The average number of working hours per day for surface laborers under these conditions, is about 9.5. Owing to the large number of holidays the number of working-days per year is but 277.

In 1900, 1,325 laborers were employed in and about the mines of the Nicopol district, exclusive of the peasants engaged in transporting the ore. These latter at times number 800 or 1,000.

FIG. 2.—PLAN OF THE WORKINGS OF THE SOFIA MINE.

**Mining.**—The mines near Salt river are opened mostly by tunnels or adits extending into the gently sloping hillside that forms the southern slope of the shallow river-valley, but in one or two instances the workings are reached by vertical shafts at points some distance up the slope of the hill, from the outcrop of the bed. The practice is to open the deposits by main and secondary gangways, which extend at right angles to each other, and thus subdivide the bed into rectangular blocks, as shown in Fig. 2. *AA* representing the main gangways, and *BB* the secondary gangways. The main gangways are wide enough for double tracks and are of sufficient height to permit the passage of horses. The secondary gangways accommodate a single track and are high enough only for hand tramming. As the overlying clay will not stand unsupported for any considerable time, the gangways are closely timbered as driven. As a rule, however, it is necessary to lag only the backs, leaving the sides open.

Stopes are opened from the secondary gangways, and the ore trammed by hand to the main gangways, thence it is taken by horses to the shaft or tunnel-mouth. The main gangways should be placed a proper distance apart in order to avoid excessive cost for hand-tramming, but in most instances that have come under my observation, they are spaced too far apart for the best results. The secondary gangways are commonly spaced about 70 ft. between centers, leaving the shortest dimension of the blocks into which the bed is subdivided, about 64 ft. As the surface of the clay underlying the ore deposit is substantially a horizontal plane, the floors of the openings are kept at this level, and when the required height of an opening is greater than the thickness of the ore bed, the overlying clay is removed.

The ore body having been opened in this manner, stoping is commenced in the blocks most remote from the shaft or main tunnel. The work of stoping consists in driving short drifts into the blocks, from the secondary gangways. These drifts are opened in pairs from any secondary gangway, as at CC, Fig. 2, one drift being opened in the block on the right-hand side of the gangway, and the other directly opposite, in the block on the left-hand side. The stoping drifts are about 32 ft. long, and extend halfway through the block, where they meet similar drifts driven from the secondary gangway bounding the opposite side of the block. The native practice was to make the stoping drifts about 5.25 ft. wide, but by increasing them, wherever the ground permitted, to a width of 7 ft. the product of ore per man per day was largely increased. The height of the stoping drifts is equal to the thickness of the ore bed, none of either the overlying or the underlying clay being removed. The stoping drifts are closely timbered and the backs lagged. A pair of stopes having been opened near the center of two adjacent blocks, and the ore removed, the timber is pulled out, which allows the overlying clay to fall in and fill the opening. This usually occurs immediately upon removal of the timber, but in some instances the clay is so firm that it stands for a short time unsupported. In this operation of filling the stopes, as much of the timber as possible is saved for subsequent use, as, the region being remote from sources of timber supply, its cost is the largest single item in the expense of mining. The saving of timber was encouraged by the payment of premiums, and from 60 to 70% of the timber employed in the stopes was regained. A pair of stopes having been opened and filled, another pair is opened directly adjacent, and the operation repeated, until the whole bed is removed over the area embraced by the opening work. Stoping is done by parties consisting of two men, one mining the ore and the other trammed it to the main gangway. They are paid by the car, and as miner and trammer exchange places from time to time, each shares equally in the proceeds of the work. Timber is supplied them, but they are required to put it in place. Lights (candles) and other supplies are charged to them and deducted from their gross earnings, which include in addition to the rate per car, the premiums on timber saved. All implements are furnished by the operators. The ore is trammed underground in small cars running on steel rails, holding about 15 cu. ft., or slightly over half a ton of ore. They are filled in the stopes and go without rehandling to the dump.

The mines at Salt river are at a slight elevation above the river, and are almost

perfectly dry, except after prolonged seasons of heavy rain, when some inconvenience from water is occasionally experienced.

The ore is mined with a pick, and under the methods described, the average daily production of each miner is about 10 tons. The average daily quantity handled by the trammers is of course equal to that produced by the miners. Considering the very favorable conditions for mining, the results obtained by the miners seem small in comparison with those that would probably be reached under similar conditions in the United States, and by the same standard of comparison, the work accomplished by the trammers appears even more unfavorably; but as the day's wage of the miners is less than one-third and that of the trammers but little over one-third of that paid similar labor in this country, the labor costs per ton, especially that for mining, are not high.

Reference has already been made to the scarcity of timber in this region. The principal source of supply is the Government of Smolensk, from whence the timber is floated down the Dneiper to various points in the steppe region. The timber obtainable for mining purposes looks exceedingly small to one accustomed to American practice, the diameter of the largest logs not exceeding 8 in. On account of the small size of the timber, and the character of the clay overlying the ore deposit, it is necessary to place the sets much closer together than is commonly done in mining practice, the usual distance being 2·3 ft. between centers. As a rule no lagging is used on the sides of drifts or other openings, but slabs are used for the backs.

*Ore Dressing.*—At the Dneiprfsky mines the crude ore is sized by trommels, and subsequently jigged; the products have already been referred to. At the mines near Salt river, however, hand-screening and sorting alone are used for the beneficiation of the crude ore. The process at the Pocroffsky mines is as follows:—

1. The crude ore is screened, separating it into two classes.
  - (A) That above 0·5 in. in diameter.
  - (B) That below 0·5 in. in diameter.
2. Class A is then cleaned as described below, and hand-picked, yielding a product locally called "large" ore, which amounts to about 12% of the weight of the crude ore extracted from the mines. It contains about 47 to 48% Mn on sample dried at 100°C.
3. Class B is screened, yielding two classes.
  - (C) That above 0·16 in. in diameter.
  - (D) That below 0·16 in. in diameter.
4. Class C is hand-sorted, which separates the pieces of clay and other waste material. The shipping-ore obtained is locally known as "small" ore. It is about equal in quantity to the large ore, amounting to about 12% of the crude ore. It contains about 41 to 42% Mn on sample dried at 100°C.
5. Class D, amounting to from 66 to 75% of the crude ore taken from the mines, and containing about one-half of all the metallic manganese carried by it, forms the tailings, which go to waste. This class contains about 27% Mn on sample dried at 100°C.

om the wagons onto a stock-pile, the wagons driving on top of the latter, and loading by shoveling, or by upsetting the wagon-box, or sometimes the entire wagon.

The average price paid for transportation from Salt river to Nicopol is about 60c. per ton, while from Salt river to Pocroffsk the rate averages about 75c. per ton.

The disadvantages of this means of transportation are severely felt by the mine operators; its inherent expensiveness, the fluctuating and uncertain supply of wagons, the changes of weather with the consequent bad condition of the roads, all militate against the prosecution of the industry. It seems probable, however, that improved facilities for transportation to the Dneiper will be available in the near future, as a railroad was commenced in 1901, and will, it is expected, be completed in 1903. The route crosses the Dneiprofsky mines and passes the Pocroffsky mines at a distance of 10 versts (6.7 miles). A branch will extend to Nicopol, and a branch connection with the Pocroffsky mines is contemplated.

For further shipment the ore is rough screened and transferred from the storage places at the Dneiper to barges having a capacity of about 350 tons. The ore is transferred on stretchers, each consisting of a rectangular wooden frame, the two longest sides projecting so as to provide two handles at each end, a piece of canvas being stretched across between the two short sides of the frame, for the reception of the ore. Two men carry a load of about 180 lb. The cost of loading barges in this manner is about 8c. per ton, screening included.

If the destination of the ore is one of the steel works in southern Russia, it is usually taken from Nicopol or Pocroffsk, up the Dneiper to Alexandrovsk, and transferred to the railroad. If it is for foreign shipment, it is taken down the river to Nicolaieff, where it is transferred to ocean-going vessels.

In conclusion I desire to express my obligations to the directors of the Nicopol-Arionopol Mining & Metallurgical Co., of St. Petersburg, for permission to use the information gathered while in its employ, as well as for facts communicated especially for the present paper. Information has also been kindly given by Mr. Thomas E. Heenan, United States Consul at Odessa.

## MICA.

THE total production of sheet mica during 1901 was 360,060 lb., valued at \$98,859, a considerable decrease from the quantity produced in 1900. The total production of scrap mica during the year is estimated at 2,165 short tons, valued at \$19,719. North Carolina registered an increased production in sheet mica, but the scrap mica produced was considerably less than the production of 1900. The imports of both sheet and scrap mica increased correspondingly to the decreased domestic production, for mica may be imported from Canada and India, especially the latter country, at much lower prices than it can be obtained in the United States. The consumption of sheet mica in stoves, and of the smaller discs and irregular shaped pieces for insulation and electrical purposes has increased during the year, keeping pace with the increased production of machinery and fittings. A new use for mica scales or finely ground mica, according to U. S. Patent No. 667,488 of February 5, 1901, issued to G. H. Brabrook, of Taunton, Mass., is to combine one part of mica mixed to a thin paste with water and add about three parts of plaster of Paris. After thorough incorporation the mixture is cast on the pattern of the mold desired, dried at from 250° to 300° F. for from 10 to 12 hours, until the molds are apparently dry, when the temperature of the ovens is raised to about 1,000° F. for from 2 to 3 hours. The molds are then allowed to cool slowly. When cool molds of this kind may be used for casting metals of any kind, and are particularly adapted for small sharp castings, and also castings of considerable surface but thin and light body. Messrs. Reed & Barton, of Taunton, Mass., have obtained control of the patent.

United States Patents Nos. 686,929 and 686,930, of November 19, 1901, were issued to R. W. Heard and R. A. L. Snyder, of Pittsburg, Pa., assignors to the Mica Machine Co., of Pittsburg, Pa., for a method of and machine for the preliminary releasing or lessening of the bonds or force naturally uniting the adjacent sheets or laminae of mica. The material, after preliminary treatment, is made to adhere to a prepared surface by suitable binding material, the flakes evenly distributed, and the non-adhering ones brushed off, when the artificially formed sheet or film is ready for use.

## PRODUCTION OF MICA IN THE UNITED STATES.

(a) Not given.

*California.*—Late in 1901 a deposit of mica of the muscovite variety, with a mica schist hanging wall and granite foot wall, was discovered in the Piru mining district, Ventura County. The mica intrudes through feldspar, and consists of both mass and book mica. Active development of the deposit is promised during 1902.

*Idaho.*—The mica deposits situated in the Robinson mining district, Latah County, about 18 miles from the Northern Pacific Railway, are operated through a 600 ft. cross cut, and 500 ft. upraise, enabling the recovery of the mica at about \$5 per ton for mining. The output during 1901 was slightly greater than that of 1900.

*North Carolina.*—The output of sheet mica increased considerably during 1901, but this increase was offset by a decreased output of scrap mica. The J. E. Burleson Mica Co. was organized during the year to mine and manufacture mica at Marion.

*South Dakota.*—The Black Hills Porcelain Clay & Marble Co. made small shipments of mica from Custer County during the latter part of 1901, and early in 1902 made two 150-ton shipments. The Crown mica mine owned by the Chicago Mica Co., made regular shipments of from two to four carloads per month, to the company's plant at Valparaiso, Ind. The Daly mine, owned by the same company, is said to yield the largest books of mica of any company in Custer County. Early in 1902 articles of incorporation of the National Mica Co., capitalized at \$1,000,000, were filed. The company will work mines in Custer County.

*Canada.*—The Mica Boiler Covering Co., Ltd., of Toronto, with factories in Montreal and London, England, is the principal home consumer of Canadian mica. The factory at Montreal employs about 50 workers and consumes daily one ton of crude mica. The mica is cleansed by machinery of special design, and is then made into the required products in other sets of machinery. The mica mines of Quebec produce annually large quantities of white and amber sheet mica, besides a considerable quantity of the small flakes used in electrical insulating material. The mica mine at Perkins Mills, Quebec, owned by Messrs. Blackburn Bros., of Ottawa, is the largest producer in Canada. Its output during 1900 amounted to over 200,000 lb. of thumb trimmed mica, while that of 1901 was slightly larger. The shipments from Quebec during 1900 were, in detail: 338,200 lb. of 1-3 in. mica, valued at \$31,860; 92,359 lb. of 2-3 in., valued at \$18,534; 71,332 lb. of 2-4 in., valued at \$24,953; 25,637 lb. of 3-5 in., valued at \$15,706; 11,762 lb. of 4-6 in., valued at \$11,451; 1,995 lb. of 5-8 in., valued

at \$2,696; total, 541,285 lb., valued at \$105,200. Besides the above there were still in hand 64.5 short tons of thumb trimmed mica, valued at \$33,400, forming a total product of 335 short tons for 1900, valued at \$138,600, not including stocks of raw mica at the mines. The total production of mica for Canada for 1901 was valued at \$160,000, against a value of product during 1901 amounting to \$166,000.

*India.*—The Madras Board of Revenue, early in 1902, amended the rules for mica mining in the Nellore district to conform to the general mining rules of the Government of India. This action was made necessary by the fact that speculators had located and obtained mining leases which they had no intention of working, and held for merely speculative purposes to the restriction of the genuine operations of the district. Applications for mining leases must now be accompanied by a deposit of 500 rupees, or such sums as the discretion of the Government may determine.

### THE MICA INDUSTRY OF NEW HAMPSHIRE.

BY ALBERT J. HOSKINS.

THERE are at the present time in this State about 300 abandoned properties, 50% of which should pay a fair percentage on money invested, if they were legitimately operated. Yet companies owning these properties cannot give a good title on account of litigation or obstructive agreements entered into by their stockholders.

The two companies situated in Groton, the Palermo and the Valencia mica mines, both of which were operated several years ago, were operated legitimately for a number of years, and the immense output obtained yielded handsome profits, also the old Ruggles mine, of Grafton, and the Alstead, of Cheshire County, were dividend payers, when the work was honestly carried on. But even these properties which were once so valuable and have produced mica output valued at over \$1,000,000, are so tied up with litigation and stock-jobbing corporations that it is impossible to get a title that would warrant the investment of capital.

There are still several good prospects in this State that would undoubtedly bring good returns if properly managed, and if not incorporated under fictitious values. New Hampshire, according to statistics, has furnished more mica than any other State in the Union, having furnished at one time 80% of the annual production of the United States. Its mica has always had the preference in the open market for excellence in quality. The present discouraging conditions undoubtedly will shortly be overcome and New Hampshire will again rank as the leading producer in the United States.

The Union Mica Co., of New York City, owns the only plant operated in Groton during 1901, which is wholly engaged in the manufacture of mica specialties used in connection with electrical insulation. The product is known as compressed mica or mica-board, and is made from refuse mica. The process of manufacture is a simple one. The mica is first split up into very thin slices and built up in a form to the desired thickness, shellac being used between each piece

in the form of cement. It is then subjected to a pressure of 2,000 lb. to the sq. in., and pressed to a definite thickness. It is next steamed and placed in a mold to procure the required shape, and completed by placing in a kiln and firing.

A large number of molds and forms are necessary for the making of various shapes required by the trade. The amount of crude mica necessary for the manufacture of mica-board specialties is very small, one ton of waste mica will sometimes make finished material valued at \$1,000, labor being the greatest item.

Of the two mines in operation during 1901 and 1902 in Alstead, the Davis mine, which is the property of the Davis Mica Co., of Keene, employs about 10 men, and averages to produce one ton per day, which is customarily sold in the rough. The mica after being blasted out undergoes a hand dressing (rifting), in which operation the refuse or cracked and stained mica is split off. The remaining clear and free splitting mica is trimmed and assorted to four grades or sizes. No. 1 grade measures either 4×6 in. or 6×8 in., and sometimes larger. No. 2 grade averages from 3×4 in. to 4×6 in. No. 3 grade averages from 2×4 in. to 3×4 in. No. 4 grade averages from 1 in. to 2×4 in. Mica of No. 4 grade is known and sold as rough trimmed mica. The waste or trimmings are sold to the mills for grinding purposes at from \$15 to \$20 per ton.

The old Bowers mine, owned by Henri Picard & Co., of New York City, is operated on a larger scale than the Davis mine. About 25 men are employed in the mines and mills, the average output of the mines being two tons per day. Eighty per cent of this product is ground at the mills into grades ranging from 10 to 200 mesh to the inch. The grade most in demand is No. 40, which is used extensively in the manufacture of electrical insulating buttons, over 300,000 per annum being absorbed for this purpose. Owing to the changes of style in wall papers during the past two seasons, the demand for mica ground to 50 to 200 mesh to the inch is declining. The demand for the coarser grades meanwhile is increasing steadily. The prices in June, 1902, for ground mica ranged from \$40 to \$100 per short ton, f. o. b. mills.

## MOLYBDENUM.

THE production of molybdenum and ferromolybdenum in the United States during 1901 amounted to 35,000 lb. and 16,000 lb., respectively. The price for molybdenum metal ranged from \$1.55 to \$2 per lb.

The production of molybdenite in the United States during 1901 amounted to but 10 or 15 long tons which, however, furnished but a very small proportion of the domestic consumption of the metal. The value of the production varied from 10c. to \$1.10 per lb., and to be marketable the ore must contain over 45% Mo and must be free from copper. The average price of an ore containing from 50 to 55% Mo is about \$400 per ton. The demand for the metal molybdenum has been largely increased in recent years due to the property possessed by the metal to render chrome steel self-hardening. It is claimed that the self-hardening property can be imparted to chrome steel by the addition of one-half the quantity of molybdenum, as compared with tungsten.

L. F. Kollock and Edgar F. Smith<sup>1</sup> precipitate molybdenum electrolytically from solutions acidified with  $\text{H}_2\text{SO}_4$  or  $\text{HC}_2\text{H}_3\text{O}_2$  as a black, adherent coating of hydrated molybdenum sesquioxide which is dissolved in  $\text{HNO}_3$ , ignited and weighed as molybdic acid. Analyses of molybdenite may be hastened by applying this method to the aqueous solution of the fusion with  $\text{Na}_2\text{CO}_3$  and  $\text{NaNO}_3$ , with the precaution to use  $\text{HC}_2\text{H}_3\text{O}_2$  if sulphur is to be determined.

The volumetric determination of molybdenum steel is described by F. T. Kopp.<sup>2</sup> Dissolve 0.5 g. of the sample in a large platinum crucible with 2 c.c. of  $\text{H}_2\text{SO}_4$  (sp. gr. 1.58) and 12 c.c. of water, evaporate and add 30 g. of fused  $\text{KHSO}_4$ , fuse carefully, cool and dissolve in 500 c.c. of hot water; digest at boiling point until solution is clear, add 100 c.c. of ammonia and make liquid up to a liter. After mixing remove precipitate by passing through a dry filter; take 500 c.c. of the filtrate, add 40 c.c. of  $\text{H}_2\text{SO}_4$  and reduce the solution by passing through a column of zinc (Jones reductor). Add 10 c.c.  $\text{H}_2\text{SO}_4$ , filter and titrate the reduced molybdenum in the solution with permanganate. A blank test is made with a solution containing 450 c.c. water, 50 c.c. ammonia and 40 c.c. of  $\text{H}_2\text{SO}_4$  as a check for the errors caused by the impurities in the zinc. A similar process is used for ferromolybdenum with the exception that at first 0.5 g. of the sample is dissolved in 15 c.c. of strong  $\text{HNO}_3$  before evaporating with  $\text{H}_2\text{SO}_4$  without the addition of water.

Molybdenum alloys are produced in the electric furnace by the reduction of molybdenum oxide with oxides of other metals as described under the caption "Tungsten," elsewhere in this volume.

<sup>1</sup> *Journal of the American Chemical Society*, August, 1901, pp. 669-671.

<sup>2</sup> *Ibid.*, February, 1902, pp. 186-188.

## MONAZITE.

The production of monazite in the United States during 1901 amounted to 748,736 lb., valued at \$59,262, as compared with 908,000 lb., valued at \$50,680 in 1900. While the output of 1901 is less than that of the previous year it is of greater value, due in part to the better quality of product, which was more highly concentrated, and in part to the increased price. It is quite probable that the thorium content of the output of 1901 equalled the larger output of 1900. The greater part of the output of 1901 was obtained from Burke and Cleveland counties, N. C., although small quantities were also obtained from McDowell and Rutherford counties, N. C., and from South Carolina. Early in 1902 a tract of 353 acres of monazite land near Ellenboro, Cleveland County, N. C., is reported to have been purchased for a number of German manufacturers. The prospect for an increased production of monazite during 1902 is very promising. The demand for Carolina monazite has increased on account of the increased price of the Brazilian product resulting from the recent control by one concern of practically all the monazite properties in Brazil.

PRODUCTION OF MONAZITE IN THE UNITED STATES.

| Year.     | Quantity. | Value.  | Year.     | Quantity. | Value.  |
|-----------|-----------|---------|-----------|-----------|---------|
|           | Pounds.   |         |           | Pounds.   |         |
| 1898..... | 130,000   | \$7,600 | 1898..... | 150,000   | \$7,500 |
| 1899..... | 730,000   | 45,000  | 1899..... | 330,000   | 18,480  |
| 1900..... | 1,900,000 | 114,000 | 1900..... | 908,000   | 48,805  |
| 1901..... | 748,736   | 59,262  | 1901..... | 748,736   | 59,262  |
| 1902..... | 40,000    | 2,000   |           |           |         |

The following is a recent analysis of monazite from New Granada which has been reported by Nicholas J. Bluman:  $\text{Ce}_2\text{O}_3$  25.02%,  $\text{La}_2\text{O}_3$  22.41%,  $\text{ThO}_2$  18.00%,  $\text{MnO}$  1.21%,  $\text{CaO}$  2.13%,  $\text{SnO}_2$  3.00%,  $\text{P}_2\text{O}_5$  28.23%, Fe, Zn, S, traces; total, 100.00%. The sp. gr. of the mineral is 6, hardness 5, and color reddish-brown.

According to United States Consul-General Richard Guenther, of Frankfort, under date of April 7, 1902, the Brazilian Government has recently granted to a German, for 10 years, the exclusive right to develop the monazite-sand deposits along the coast of Brazil, and a company is being organized at Berlin to acquire control of this privilege and to exploit similar deposits elsewhere.

## PRODUCTION OF NATURAL GAS.

By F. H. OLIPHANT.

THE total value of natural gas produced and sold in the United States during 1900 was \$23,606,463, of a quantity of the value of \$23,156,616 was sold in the Appalachian and Lima-Indiana fields east of the Mississippi river, leaving \$449,847 to represent the sales west of it, which amounts to less than 2% of the total sales. The value of natural gas used in the United States is gradually increasing, the production for 1901 is estimated at \$27,500,000, which is almost 40% of the value of the crude petroleum produced for the same time, and represents a delivery of 171,875,000,000 cu. ft. of a fuel equivalent of 8,500,000 tons of coal. This amount of natural gas is drawn from 12,000 wells, and distributed through 24,000 miles of main line pipe from 2 to 36 in. in diameter. The consumption of natural gas in the United States has been greatly increased in those sections which are favorably located in respect to the gas supply. Although many of the older pools have been practically exhausted, newer ones are being discovered and an extension of the pipe-line systems, both in length and capacity, has been all that was necessary to maintain a supply for the increasing demand of the consumers. Kansas will show a large gain in its yield over the previous year, and West Virginia, with its immense areas of deeply buried sandstones saturated with natural gas under enormous pressure, has each succeeding year furnished an increased supply. The full value of this ever ready and convenient fuel will only be appreciated when it can no longer be obtained.

Hand in hand with the production of petroleum, that of natural gas occurs in the Appalachian and the Lima-Indiana field. The two are invariably associated, and have a common source. The gas occupies the higher portions of the arched rock-sealed reservoirs, while the petroleum, from its greater gravity, seeks the lower level in the same strata. It is to be regretted, however, that in many of the older gas fields of Pennsylvania, Ohio, and Indiana, the great natural store of this most precious fuel has already escaped through the numerous drilled wells that have punctured it, and immense quantities have been wasted by the careless and extravagant manner of its use when first introduced. The lesson of its value was learned too late in many cases to preserve but a fraction of what was originally pocketed and sealed in the reservoirs of the rocks. When first found it was allowed to blow off into the atmosphere with a noise that was appalling,

an extravagance that was shameful. All other fuels need some preparation fit them for combustion, but with natural gas none is necessary. The supply gas is easily regulated, and it is ever ready as a source of the most economical power when exploded in the gas engine, and, in connection with the Welsh mantle, is a source of a most brilliant and inexpensive illuminant unequalled by any other artificial light. It may rightly be classed as the source of the most economical and efficient heat, light, and power known in nature. As a source of power it has been demonstrated to be more economical than the most efficient triple expansion engines, and its economical method of transportation in pipes of large and small diameters has brought it into many thousands of households in western New York, western Pennsylvania, eastern, central, and western Ohio, and eastern and northern Indiana. It is also an ideal fuel in the manufacture of steel, iron and glass, and is an ideal fuel for furnaces.

Natural gas is especially valuable to the petroleum producer. It is generally associated with petroleum, often in the upper strata of the same well, and can be taken from the casing-head of the nearest producing well; it thus becomes a source of most economical power for pumping a group of wells. From 30 to 50 wells in many localities are operated by a single gas engine. There is no boiler required; the constant attention of an attendant, as all that is necessary with a gas engine is at intervals of from six to ten hours to be sure that the lubricating cups contain sufficient oil.

When the pressure has failed to some extent in the gas wells, by reason of withdrawal of large quantities, and the capacity of the pipes to convey the gas to market thereby lessened, large pumping or compressing plants have been erected. Many of these plants are models of the highest mechanical efficiency. The more recent compressors are of large capacity, and use the natural gas itself as a motor in driving the gas to the points of consumption. These compressors run entirely with the boiler, develop 1,000 H.P., and weigh as much as 100 tons. A careful test made by experienced engineers of one of these large compressor engines of natural gas used in Pennsylvania, demonstrated that less than 10 cu. ft. of natural gas at or near atmospheric pressure developed 1 H.P. An illustrated description of this type of engine is given elsewhere in this section.

TABLE SHOWING THE COMPARISON OF COAL AND NATURAL GAS PER INDICATED HORSE POWER PER HOUR.

| Type of Engine.                                 | Equivalent of Gas and Coal to produce 1 H.P. per Hour. |         |
|-------------------------------------------------|--------------------------------------------------------|---------|
|                                                 | Gas.                                                   | Coal.   |
|                                                 | Cubic Feet.                                            | Pounds. |
| Natural gas engine.....                         | 13                                                     | 1.3     |
| Triple expansion condensing engine.....         | 16                                                     | 1.6     |
| Double expansion condensing engine.....         | 20                                                     | 2.0     |
| Single cylinder and cut-off.....                | 40                                                     | 4.0     |
| Very high pressure, no cut-off.....             | 75                                                     | 7.5     |
| Steam oil well drilling and pumping engine..... | 180                                                    | 18.0    |

All natural gas has a high calorific power. It is composed of 93 to 97% of marsh gas ( $\text{CH}_4$ ) which requires for the latter percentage 10.5 times the volume

of ordinary air for complete combustion under the boiler or in the cylinder of the gas engine. Under boilers properly proportioned to their work in ordinary condition, 1 cu. ft. of natural gas has evaporated 1 lb. of water from and at 212°F., which gives 966 B.H.U. to the cu. ft., or 16 cu. ft. of natural gas equal to 15,456 B.T.U., the calorific value of 1 lb. of petroleum. Therefore 16 cu. ft. of natural gas have the same value under similar boilers, as 1 lb. of petroleum; or 16 cu. ft. of gas will equal the calorific value of 30 cu. in. of petroleum.

In the combustion of natural gas the best results have been secured from burner with a series of small openings about 0.0625 in. ( $\frac{1}{16}$  in.) to 0.1563 in. ( $\frac{1}{8}$  in.) or less in diameter, under a pressure not greater than from 4 to 6 in. to the sq. in. This is conveyed through a tube 1.5 in. in diameter and 16 to 18 in. long surrounding each jet of gas, with proper openings at the bottom of the tube to admit the air. It is constructed on the principle of the old Bunsen burner, with which every student is supplied at the beginning of instructions in analytical chemistry.

#### THE PRODUCTION OF NATURAL GAS IN THE UNITED STATES.

By W. H. HAMMON.

NATURAL gas is the most perfect and convenient fuel known. It is found in nature perfectly prepared for use, stored in immense reservoirs under such high pressure that, when tapped by the drill, it furnishes the power to transport itself hundreds of miles through pipe-lines to the consumer. No artificial gas compares with it in heating power, 1 cu. ft. of it being sufficient, with proper appliances, to evaporate a pint of water. It is instantly available for use by merely turning the valve and the fire can be extinguished the moment the service is completed. When properly burned, it leaves no soot, ashes or other residue.

Among some of the nations of Asia, notably China and Persia, the use of natural gas "antedates authentic history," and in the United States, its existence has been known for more than a century. In 1775, General Washington, while locating lands received in payment for military service, visited a burning spring on the Great Kanawha river near the site of the present city of Charleston, W. Va. He pre-empted the tract containing the spring and dedicated it, together with an acre of surrounding ground to the public forever.

The first recorded use of natural gas in the United States was in 1824, at Fredonia, N. Y., where it was piped from a well to illuminate the village inn in honor of the visit of General de Lafayette.

A few years later, in 1841, William Thompkins struck a large flow of gas just above the burning spring in the Great Kanawha valley, and used the gas for heating salt furnaces. Early in the history of oil-well drilling, which began in 1859, the waste gas which almost invariably escapes from oil wells was used for firing the boilers of the drilling engines, and it was very soon piped to houses of the oil producers, where it was used for light and fuel, and large out-door flambeaus were burned at the wells. In 1872, the first natural gas plant was formed, and a 2-in. line laid from the Newton well to furnish gas for domestic use in Titusville, Pa., five and a half miles distant, but it was not until 1874

that its great value as a manufacturing fuel was demonstrated. In that year Messrs. Rodgers & Darchfield began to burn it under boilers and for all the puddling and heating furnaces in their plant at Leechburg, Armstrong County, Pa. The advantages and conveniences were at once apparent, and the use rapidly increased. By 1887, 96 rolling mills and steel works were either wholly or in part supplied with this fuel, and by 1890, it is estimated that it displaced annually 10,000,000 tons of coal.

In the earlier days of its production, the original "rock" pressure of the wells (the pressure of the reservoirs as shown by closed-in wells) was so great and the producing area so extensive that the supply of gas was believed to be practically inexhaustible. As a result the gas was wasted in the most extravagant manner. Wells were permitted to discharge their product into the air and little or no effort was made to check the flow. Frequent escape pipes and flambeaus were provided to lessen the pressure on the pipe-lines and to consume the surplus gas. No effort was made to measure the amount furnished to a consumer, and as a consequence it was burned in a very wasteful manner. However, between 1885 and 1890, the earlier fields began to show unmistakable evidences of depletion, and as a result, the gas became more valuable. Meters and other saving appliances were employed and, while the quantity of gas consumed probably decreased in five or six years to less than half the former yield, the price was increased to such a degree that the total value of the product showed but little decline. Since 1895 the value has increased, and since 1898 both the amount and value of gas consumed has increased until in 1901 the value of the product probably exceeded \$25,000,000. The amount sold in 1900 was 127,000,000,000 cu. ft., and if the rate of increase continued during 1901, as the statistics of some of the largest gas companies indicate, the amount consumed was 150,000,000,000 cu. ft., equivalent to one cubic mile. The largest gas holder yet constructed is of 5,000,000 cu. ft. capacity, and the supply during 1901 would be sufficient to fill it 30,000 times, an amount which would furnish nearly 1,000 cu. ft. per month to every family in the United States.

#### GAS WELLS.

The supply of gas is obtained from more than 10,000 wells of depths varying from a few hundred feet to more than 3,000 ft., and of an aggregate depth which would penetrate from the surface almost to the center of the earth. Three thousand miles of casing and tubing are in these wells.

The rock pressure of these wells varies greatly. In old, depleted territory it is practically nothing, and the only way of securing an additional supply is by diminishing by means of pumps the pressure at the mouth of the well below that of the atmosphere. However, in new fields, especially those drilled to the deeper sands (2,500 to 3,500 ft. deep) the pressures frequently exceed 1,000 lb. to the sq. in. Some of the largest wells known, if unconfined, would discharge into the air at least 25,000,000 cu. ft. per day, although an average "open flow" volume is probably not more than 250,000 cu. ft. The quantity actually obtained is but one-fifth of this amount, as most wells discharge against more or less line pressure and under normal conditions quite a large proportion of the wells

are "shut in" as a reserve supply until needed. The roar resulting from the "blowing off" of some of the largest wells into the open air is terrific. Formerly it was considered impossible to shut in some of the largest wells until they had become partially exhausted. It was several months after the "Big Moses" well in Tyler County, W. Va., was "struck" before it was controlled. The roar was so great that voices could not be heard within 200 ft. of the well. When the Robinson well, in Wetzel County, W. Va., was struck, six years ago, it was deemed unsafe to confine the gas, and the pipe-line was laid to the well, the connection made, and the gas turned into the line, without shutting in the well. The gate on the well was not closed until four years after it was drilled. In 1844, while drilling a salt well in West Virginia, near the burning spring referred to above, so strong a flow of gas was struck that it threw the drilling tools, weighing about 1,000 lb. out of the hole. Since then there have been several instances of much heavier tools being forced out of the hole by the pressure.

#### DRILLING WELLS.

The means employed in drilling gas wells are identical with those in use in drilling oil wells. When the location is selected a rig is erected which consists of a derrick about 80 ft. high, an engine house and a connecting belt house. From the main sill of the derrick a strong Sampson post is erected, upon which is balanced the walking beam. This is operated by the engine connected at one end, while from the other end the tools are suspended by a strong cable, one end of which passes over the crown pulley in the top of the derrick and is then attached to the bull-wheel shaft, a huge windlass at the side of the derrick. The free end passes down the well and to it the drilling tools are attached. A temper screw connects the cable and the walking beam consisting of a long screw attached to the cable, while its nut and "reins" are attached to the walking beam so arranged that by turning the screw the tools are lowered into the well. The tools proper consist of a rope socket, jars, auger stem and bit. Altogether a string of tools used for drilling deep wells is between 60 and 70 ft. long and weighs about 4,000 lb. The drilling bit is a heavy, blunt, chisel-shaped steel drill. The only other tool in the string worthy of especial mention is called the "jars"; these are two strong links arranged to admit a free vertical movement of two or three feet.

In operation, the walking beam alternately raises and lowers the tools, which are so adjusted that when the beam is at its maximum elevation, the bit is elevated about a foot above the bottom of the hole. Then as it falls, the bit first strikes the rock a sharp blow, due to its own weight and that of the stem. The slack resulting from the remaining fall of the beam is taken up in the jars, the links of which thus separate several inches. As the beam rises, the cable is first lifted until the slack in the jars is taken up when the tools receive a sharp tap which loosens the bit from the rock and permits it to rise for the next blow. As the drill cuts the rock, it is lowered by revolving the temper screw at the top of the well. When the screw is run out, the cable is loosened from the temper screw and wound up on the bull-wheel shaft, thus lifting the tools out of the hole.

The bailer is then lowered and the drillings removed. The tools are again inserted and the drilling progresses as before.

In southwestern Pennsylvania and West Virginia the hole is first made about 15 in. in diameter to a depth of about 15 ft. and a conductor inserted. Below this is drilled a hole about 13 in. in diameter through the principal Coal Measures and a 10·25-in. casing is inserted to case out the sulphur water found in the coal. A 10-in. hole is then sunk for 500 ft. to 1,500 ft. through the salt sand which frequently contains vast quantities of water and the 8·25-in. casing is inserted. Inside this is then drilled an 7-in. hole until what is known as the "Big Injun" sand is reached at about 1,500 to 2,000 ft. when the 6·625-in. casing is inserted. Below this point the hole usually remains dry, and a hole about 6·5 in. in diameter is continued to the bottom. However, it is still sufficiently large to admit of inserting a 5·1875-in. casing if the conditions should require. The cost of drilling a well, including the rig, casing, etc., varies from about \$1,500 in the shallowest territory, to nearly \$10,000 in the deepest sands of West Virginia.

#### PIPE LINES.

In the handling of natural gas a system of pipe-lines is necessary to connect the producing wells and the cities and towns where the gas is consumed, as well as an additional system to distribute the gas throughout the cities to the individual consumers. In the earlier period of the industry it was not believed possible to conduct gas at high pressure for great distances, and in the light of present knowledge it seems incredible that less than 25 years ago it was believed by a few that gas, being elastic, could not be forced through lines at high pressure, under the erroneous idea that the friction on the sides would retard the flow, while the continued inflow would increase the pressure sufficiently to burst the pipe.

In 1881, Spang, Chalfant & Co. piped gas from Millerstown, Pa., to their mills on the Allegheny river opposite Pittsburg. One of the first large gas mains of any considerable length was laid in 1882, by Mr. J. C. McDowell for the United Pipe Lines, which have since been included in the National Transit Co. It was an 8-in. line 20 miles long, connecting a well near Wilcox, with the pumping station at Colegrove, McKean County, Pa., where it supplied the boilers. About the same time, a line was laid from McKean County, Pa., to Buffalo, N. Y. Between 1882 and 1885, natural gas came into general use in most of the cities and villages of western Pennsylvania and southwestern New York.

As the adjacent fields became depleted, the gas has been brought from greater and greater distances through pipe-lines until at the present time Pittsburg is receiving gas from Doddridge County, W. Va., more than 100 miles distant; Akron and Canton, Ohio, from Wetzel County, W. Va., a distance of 150 miles; and Chicago from central Indiana. Arrangements to conduct gas more than 200 miles from the source of supply are now reported to be in progress.

The pipes used for these conductors vary in size from 2 in. to 3 ft. in diameter. For the most part the pipe is wrought iron or steel. The smaller pipes (10 in. in diameter and under) are usually made of screw-joint pipe, although in the last few years plain end pipe with couplings and rubber packing has become very popular, and is in a large measure taking the place of screw pipe, it being

equally cheap in cost and is more readily laid. Sizes from 10 in. to 2 ft. in diameter are frequently laid with "Converse" pipe, which consists of plain end pipe with the joints of heavy cast-iron sleeves or hubs fitted by molten lead which is caulked into the space between the pipe and the sleeve. The disadvantage of this joint is one common to all lead joints in that the packing material, being inelastic, becomes loosened by the settling of the pipe and by the slight movement due to changes in temperature. By a re-enforcement with rubber packing pressed against the outside of the joint by iron clamps, a very satisfactory connection is made, and frequently a pipe-line of this construction has been operated to upward of 300 lb. pressure to the sq. in. Pipes above 2 ft. in diameter are either cast-iron water-pipe or steel pipe riveted after the method of boiler plating. A line of riveted steel pipe, 36 in. in diameter, extends from Pittsburg 20 miles to the southward, and cost to construct approximately \$50,000 per mile. In times of maximum demand it passes daily over 100,000,000 cu. ft. of gas.

The length of pipe of all sizes in the various transportation systems of this country is from 15,000 to 20,000 miles. In addition there are from 7,000 to 10,000 miles of pipe in the various distributing systems in cities using natural gas. Thus in the aggregate there is approximately 25,000 miles of natural gas pipe-lines in operation.

#### PUMPING MACHINERY.

For the most part the power necessary to transport the gas through the pipe-lines is furnished by the natural rock pressure of the wells. In many places however the well pressures are so nearly exhausted, or the distances to be transported are so great, that this source of power is insufficient, and it is necessary to supplement it artificially by pumping. Where the pressure is small and the lift 10 lb. or less, as in drawing gas from depleted territory for nearby consumption, some form of rotary blower has been used successfully, but for higher pressures a cylinder gas compressor is necessary. Among modern gas pumping machinery are some of the finest specimens of mechanic art. Probably nowhere has a greater amount of work been done with the same expenditure of fuel than has been accomplished in gas compressors; in fact, it is doubtful if the results have been equalled in any other power plants. An indicated horse power has been maintained for one hour with less than the equivalent of two-thirds of a pound of coal. Thirty cubic feet of gas have been compressed from atmospheric pressure to 270 lb. gauge pressure with the expenditure of but 1 cu. ft. of gas in producing the power. This result was, of course, obtained only by the use of a gas engine. The importance of this new design of engine to the natural gas industry is so great that a complete description of it is warranted; the one given below has been furnished through the courtesy of Mr. E. C. Lufkin, of the Snow Steam Pump Works.

The machine illustrated by the half-tone photographic cut (Fig. 1) is designed by Mr. John S. Klein, of the National Transit Co., Oil City, Pa. This engine has four single-acting power cylinders 25 in. in diameter of bore  $\times$  48 in. stroke, two first stage compressor cylinders 31 in. in diameter  $\times$  24 in. stroke, and two second stage compressor cylinders 15.25 in. in diameter also 24 in. stroke.

and t

Fig. 2. 1000-H.P. Gas Compressor, operated by a Gas Engine, at Hubert, McKesson Compressor Co.

It will be noticed by referring to the illustration that two of the power cylinders are placed on one side of the main shaft and two on the opposite side, all being connected to the same crank pin by means of crossheads working in suitable guides and suitable connecting rods. The four power cylinders being single acting and each 4-cycle, give an impulse every stroke, so that the distribution of power is the same as though a double-acting steam cylinder were used in place of the four gas-power cylinders.

The main shaft is of the center-crank type and has two cranks, one connecting with the power cylinders and the other to the compressor pistons. The compressor crank pin stands at an angle of  $90^{\circ}$  from the power cylinder crank pin, so that the greatest turning moment derived from the power cylinders and the greatest resistance of the compressor cylinders are coincident. This arrangement necessitates the use of very small flywheels, there being two on this machine, each being 3 ft. in diameter and weighing about 37,000 lb. The connection on the latest of these machines from the outboard power piston to the inboard one is made by a central piston rod passing through a water-jacketed stuffing box in the outboard head of the inboard cylinder. The piston rod is also water-jacketed, it is hollow and forms the water-duct for the circulation of jacket water through the power pistons, which also are water-jacketed.

On the first of these machines the mixture was throttled by a speed governor so designed as to be changed for varying speeds. With this appliance every fourth stroke was an impulse stroke and the amount of mixture admitted depended upon the amount of power required to keep the speed of the engine at a constant rate. The later engines built of this type were however fitted with a cut-off valve which shut at a point in the stroke determined by the speed governor, and admitted sufficient gas to maintain constant speed.

The engines are started in the following manner: An auxiliary gas engine, placed in a separate engine house, is connected to a small mixture compressor which compresses the proper mixture of air and gas into a storage tank at about 90-lb. pressure. When it is desired to start one of the main engines, the mixture under the 90-lb. pressure is admitted to one of the power cylinders on one side of the shaft, which moves the piston over into its other extreme position. The mixture is then allowed to escape from this end of the cylinder, leaving it full of the mixture at atmospheric pressure only. The engineer then goes to one of the power cylinders on the opposite side of the shaft and admits the mixture to this cylinder forcing the piston over into its other extreme position and compressing the mixture in the cylinder in which the mixture was first admitted. The mixture is then allowed to escape from this second cylinder, leaving it full of the mixture at atmospheric pressure. The engineer then returns to the first cylinder and trips the electric igniter, combustion ensues and the engine starts, the igniter in the second cylinder being operated automatically by the movement of the engine. The machine is started in this manner with very little difficulty. The inlet and exhaust valves on the engine are steel castings, the exhaust valve being water-jacketed internally. Engines of this type are run continuously at speeds varying from 80 revolutions per minute to 120 revolutions, and indicate as high as 1,500 brake H.P. Each machine is supplied with a jacket-water

power pump driven from the main engine, which supplies jacket water to the compressor as well as the power cylinder, heads, pistons, etc. Two of these machines of an entirely new design are now being built by the Snow Steam Pump Works of Buffalo, N. Y., and each will indicate about 4,000 H.P., by far the largest gas engines yet constructed.

Many very efficient steam driven compressors are in operation, which, while not as economical as the gas engine, are models of their kind. Some plants use compound engines and burn natural gas as fuel under the boilers, sustaining an indicated horse power for an hour with 16 cu. ft. of gas. A plant of this character, pumping from atmospheric pressure to 300-lb. pressure, consumes as fuel about 8% as much gas as it compresses. Whenever it is necessary to do more work than is required to compress gas from zero to 100 lb., two compressions are made. The first raises the pressure about one-fifth and the second the remainder. It may seem difficult to understand how as much work is done in compressing gas from atmospheric pressure to 50-lb. gauge pressure as from 50-lb. gauge pressure to 250 lb. The reason is manifest when it is considered that in compressing from zero to 50-lb. gauge pressure or from approximately 15-lb. to 65-lb. absolute pressure, the gas is compressed to about two-ninths the original volume, which is about the ratio that exists between the intake and the discharge volumes in the second stage, and while the piston head is working against much higher pressures in the latter case, relatively smaller cylinders are necessary to pass the same quantity of gas under the greater pressure, so that, with the same length of stroke, the total pressure against the cylinder head is the same. Since the amount of gas that can be passed through a line between two given points depends on the difference between the squares of the initial and discharge pressures, it is evident that it is much more economical to pump the gas with one high stage compression (where lines are sufficiently tight and strong) at the initial end than to relay it with several low stage compressions. In all two stage compressions it is essential to cool the gas thoroughly between the compressions, or the pressure due to the added heat will sometimes be greater in the second stage than that due to the compression of the gas.

#### GAS MEASUREMENT.

There are four methods in vogue for measuring gas, namely: (1) By meters, (2) by Pitot tubes, (3) by computation from the initial and discharge pressures and size and length of pipe-line, and (4) by computing the output of the well from the volume of the hole and minute pressure.

1. *Meters.*—The method of measurement by meter is in most frequent use. The meters for the most part depend for their operation on two principles: one is the actual measurement of the gas by passing the whole volume through pockets or bellows of given capacity which fill and empty by the movement of a series of valves operated automatically by the flow of gas through the meter. Where the quantity of gas is so great as to need very large and expensive meters thus to measure it directly, another method—the proportional meter—is used. In this device, two routes, differing greatly in size and capacity, are available for the passage of gas through the meter. The flow through these two channels is con-

trolled by a valve in each so arranged that they operate in unison, or in such a manner that the ratio between the discharge of the two branches remains constant. One of the direct measuring meters is placed in the smaller branch and the flow through it is thus measured, from which the total amount passed by the meter is easily calculated. In general use a special dial is attached to the small meter, from which can be read the entire amount of gas passed. When gas is passed through a meter at a higher pressure than the standard at which it is sold, it is necessary to make a correction to the meter reading due to the extra pressure on the gas. The usual standard at which gas is sold is 4-oz. gauge pressure, and a simple formula for reducing to this pressure is as follows:—

$$Q=q \frac{p+h}{h+1}, \text{ in which}$$

$Q$ =cubic feet of gas at 4-oz. pressure,       $p$ =gauge pressure in pounds per  
 $q$ =cubic feet as shown by meter,                      square inch,  
 $h$ =pressure of atmosphere in pounds.

Since the pressure of the atmosphere is about 14.75 lb., this becomes

$$Q=q \frac{p+14.75}{15}.$$

Self-recording pressure devices can be attached to meters operating at high pressures by means of which the average pressure and the actual quantity of gas passed can be quickly determined.

2. *Pitot Tubes*.—The amount of gas passing through a pipe-line can be quite accurately determined by means of the Pitot tube, which consists of a small metal tube inserted in the line, having its open end turned in the direction from which the gas is flowing. This tip communicates with one branch of a glass U-tube partly filled with some liquid (generally water). The other branch of the U-tube is connected to an opening in the pipe-line, the plane of which is at right angles of that of the opening into the Pitot tube. By this means the branch connected to the Pitot tube will show a higher pressure than that connected to the pressure line, due to the force of the current of gas flowing against it. This difference of pressure will be shown by the difference in level of the liquid in the U-tube. Since this force is due to the velocity and density of the gas passing, the rate of flow can be obtained, and with frequent observations, the quantity of gas passing through the line can be readily determined. The formula of the Pitot tube as applied to gas measurement has been very carefully determined by Prof. S. W. Robinson, whose report is published in the *Geological Survey of Ohio*, Vol. 6, pp. 548-594. The final formula is:—

$$Q=1,690d^2\sqrt{h \left(1+\frac{p}{15}\right)}, \text{ in which}$$

$Q$ =number of cubic feet of gas flowing       $p$ =static pressure of gas in pounds,  
     in pipe-line per hour,                       $h$ =difference in level of water in  
 $d$ =diameter of pipe-line in inches.                      U-tube, measured in inches.

This formula is computed for gas flowing through the tube at a temperature

of 40°F., but reduced to a standard temperature of 50°F. in the measurement by this formula. It is for gas of 0.60 sp. gr. To reduce to gas of any other gravity multiply the result by

$$\sqrt{\frac{0.6}{\text{Sp. gr. gas}}}$$

3. *Computation from Pressures at Two Given Points.*—It is possible to determine with considerable accuracy the quantity of gas passing through a pipe-line from the pressures at two given points when the distance between them and the size of the line are known. The formula for this purpose is:—

$$Q=40 d^2 \sqrt{\frac{(p_1^2 - p_2^2)}{LD}} \text{ in which}$$

$Q$ =cubic feet of gas passing in one hour,  
 $p_1$ =absolute pressure in pounds (gauge pressure+15 lb.) at initial point,  
 $p_2$ =absolute pressure in pounds at discharge point,  
 $d$ =diameter of pipe in inches,  
 $L$ =length of pipe between points in miles,  
 $D$ =density of gas.

Probably the most complete study of this method has been made by Mr. Forrest M. Towl, who has constructed a slide rule for determining at sight the discharge of any line.

4. *Computation of the Output of a Well from its Minute Pressure.*—A fair approximation of the output of a well at atmospheric pressure can be obtained from the capacity of the hole in cu. ft., and the increase in pressure of a well in one minute after it is shut in. The formula for the purpose is

$$Q=\frac{d^2 \times 3.1416 \times L}{4 \times 144} \times \frac{p}{15} \times 60 \times 24, \text{ in which}$$

$Q$ =quantity in cubic feet of gas discharged into the open air in twenty-four hours,  
 $d$ =diameter of hole in inches,  
 $L$ =depth of hole in feet,  
 $p$ =pressure in pounds shown by gauge one minute after closing gate (less any pressure gauge might have shown before closing gate).

Reduced to lowest terms, this becomes approximately  $Q=\frac{1}{2}d^2Lp$ , or the output of a well in one day is equal to one-half the product of the square of the diameter of the hole in inches by the depth of the hole in feet by the pressure in pounds per sq. in. Of course, if a well is tubed, the diameter of the tubing is used instead of the diameter of the hole and if the packer is above the bottom of the hole, the capacity of the tubing to the depth of packer is first obtained and to this is added the capacity for the full size of hole for the distance from the packer to the bottom of the hole.

If the output of the well is desired at any other pressure than that of the atmosphere, the gate on well is closed as before and the rise in pressure noted for one minute from the instant the pressure reaches the desired point, this amount being used for the minute pressure.

## SOURCES OF SUPPLY.

*Geologic Sources.*—Although small quantities of gas are always present in the composition of animal and vegetable matter, the principal sources of natural gas are from porous strata of rock, usually at considerable depth below the earth's face. The strata are chiefly sand, gravel, shale or limestone lying between more impervious layers. Petroleum is frequently discovered in these same strata although from much more limited areas than those producing gas. The deposits are found in various portions of the world in the strata of all periods from the Cretaceous to the Tertiary. The great gas reservoirs overlying the Cincinnati arch are located in the Trenton and Clinton limestones of the Silurian period. Those of the Appalachian system are in the Devonian. In eastern Ohio they belong to the Sub-carboniferous period. Those of the southwestern States and California are in the Tertiary formation, as also are those of Eurasia. In the oldest formations, *i.e.*, the Trenton limestone, the gas is found in the upper layers of the limestone itself and directly underneath the Utica shales. In the Clinton limestone, the source of gas appears to be a layer of sand within the limestone. The only source of gas in the Appalachian reservoirs is from layers of sand rock enclosed in limestone or slate. In the Tertiary formation, the gas comes from beds of sand which are frequently so soft as to hardly merit the name of rock. The natural gas is usually obtained from the most elevated portions of the stratum, *i.e.*, along anticlinals of the rock, while the petroleum collects on the lower horizon and frequently salt water is found on a still lower level along the synclinals of the rock. The anticlinal theory for the location of gas and oil is very thoroughly discussed by Prof. I. C. White, State Geologist, in the *West Virginia Geological Survey*, vol. 1, 1899, pp. 158-180, and by Prof. Edward Orton, State Geologist, in the *Geological Survey of Ohio*, Vol. 6, p. 89 and following. The essentials of the theory are that the natural gas, being the lighter product, collects at the top of the reservoir, formed by the porous rock under the impervious layer, while the sand and water arrange themselves in the same layer in accordance with their relative gravity.

The most prolific natural gas fields thus far developed have been (1) those along the western slope of the Appalachian mountain system extending from the Canadian border to Tennessee, and (2) those throughout the great anticlinal extending from Kentucky to and even beyond Lake Erie, known as the Cincinnati arch, with its center near Cincinnati. Between these two large deposits is a marked synclinal, which, at its lowest point near the Ohio river in northwestern West Virginia, is many thousand feet below the crest of the Cincinnati arch on one side and of the Appalachian mountain system on the other.

*Appalachian Gas Fields.*—The Appalachian gas deposits occur in the small anticlinals or anticlinals which exist in the strata as they rise toward the Allegheny mountains from the synclinal that lies to the westward. At the deepest place in this synclinal, in Wetzel County, W. Va., the Pittsburg coal drops almost to the level of tide-water. A few miles west of Pittsburg, the coal in this synclinal is about 900 ft. above tide level. In Armstrong County the rocks have a rise of 1,100 or 1,200 ft. higher, and from this region the rise is quite uniform to the New York boundary at a rate of about 32 ft. to the mile.

In lines approximately parallel with this synclinal on the one side and ranges of the mountains on the other, are a series of small folds, the tops of which are from a few feet to 300 or 400 ft. above the adjacent synclinals. In these small anticlinals nearly all the great deposits of the Appalachian have been found. The illustration (Fig. 3) shows a cross-section of the strata at the outcropping of the Pittsburgh coal near Pittsburgh.

As has been observed in the main trough between the Cincinnati arch and the Allegheny Mountains, all the strata dipped downward in a line from the north east toward the southwest. In the northern portion for the first 50 miles of the New York boundary, this dip amounts to about 30 ft. to the mile. In the next 50 miles, or to about the line of Pittsburgh, the dip is about 10 ft. to the mile, while south of Pittsburgh it does not average more than 9 ft. to the mile.

The gas deposits of southern New York and of McKean, Elk and Luzerne counties, Pa., are found in several different strata of sand in the Chemung group of the middle Devonian period. The deepest sands are those producing gas in Elk County, which are about 200 ft. below the Bradford sand. From the Bradford sand there is an in-

FIG. 3.—CROSS-SECTION OF STRATA AT OUTCROPPING COAL, NEAR PITTSBURGH.

about 300 ft. to the Cherry Grove sand, and about 400 ft. above it is located the Warren sand. The most productive sands because of their thickness are those of the Venango and Butler group. These are found from 1,000 ft. above the Warren group in the Catskill epoch of the Upper Devonian period. In Butler and Venango counties there are three distinct strata of sands with an interval between them of a little more than 100 ft. From some of the strata of this group has been obtained from Crawford southward to Kentucky. The sands are known by various names in different localities. In Crawford, Venango, Butler, Clarion and Forest counties, known as the first, second and third oil sands. In Armstrong, Allegheny, moreland and Washington counties the upper layers are known as the Hurrahsville or salt sand and the Hundred Foot sand, while the lower layer is divided into a number of strata known under names of Gordon, Gordon Stray and South of the Pittsburgh district, the Hundred Foot divides into the Third, Fourth, Fifth, and Sixth, and below the Gordon are found the Fourth, Fifth, Sixth, and Seventh Elizabeth sands in the above order. North of Pittsburgh is observed a layer of sandstone, the lower edge of which lies two or three hundred feet below the Number One of the Venango group. This layer is about 300 ft. in thick-

outcrops in Butler and Venango counties, in the latter region being found only in the hill tops, from which it secured the name of Mountain Sands. From the Pittsburg region southward it is known under the name of the "Big Injun," and is productive of gas and oil in many localities.

The strata generally increase in thickness to the southward, consequently the interval between the sands becomes greater. There is an exception to this rule, however, between Green County and Wetzel County, W. Va., where the interval diminishes slightly.

2. *Gas Deposits about Cincinnati Arch.*—The Trenton limestone of the Silurian period has an elevation at the crest of the Cincinnati arch of more than 400 ft. above tide level. From this region it rapidly falls until at Columbus, Ohio, it is 1,200 ft. below tide level, and from thence eastward the decline is very rapid, equalling 3,000 ft. to the Ohio river at East Liverpool. To the northward it declines to about 600 ft. below tide level, where the crest of the anticlinal passes under Lake Erie in Ottawa County. At Indianapolis it is 280 ft. below tide level. From the crest of the arch, in Claremont County, just east of Cincinnati, two marked anticlinals extend, one a little east of north toward Lake Erie, and the other more marked branch extends northwestward into Indiana, apparently passing through Union, Fayette, Wayne, Henry, Delaware, Madison and Grant counties. Prof. Orton concludes that the northwestern branch was first elevated and that later there extended northwestward from it what is known as the Lima axis. Near Findlay, Ohio, this meets an abrupt terrace passing due north and south, and causes the anticlinal to change direction at that point. The vast gas deposits of Indiana and Ohio are found on the northwestern anticlinal of the Cincinnati arch and along the Lima axis and the crest of the Findlay terrace.

Besides the Trenton deposits, there are those of the Clinton limestone in Fairfield and Licking counties, Ohio, which appear to be along a terrace in that rock. Also in eastern Ohio gas is obtained from the Berea sandstone of the Sub-carboniferous period.

While the principal gas deposits are along the crests of anticlinals, they are greatest where there is a considerable dip from the crest of the anticlinal downward. An essential to a gas reservoir is a layer of impervious rock above the gas horizon.

#### DESCRIPTION OF GAS DEPOSITS.

As above stated, the two great sources of natural gas on this continent are along the western slope of the Appalachian Mountains and the great Cincinnati arch. These two fields supply fully 95% of all the gas produced in North America. Besides these Kansas, Arkansas, Indian Territory, Texas, California and Colorado yield smaller quantities. The following table shows the approximate value of natural gas produced in the United States from 1892 to 1900, inclusive, and from it may be seen that the value of the gas produced in Pennsylvania has continuously exceeded that of any other State. However, for the past eight or nine years the actual amount of gas produced in Indiana has exceeded the Pennsylvania production, which is due to the fact that the price of gas obtained in Indiana has been exceedingly low. From 1888 to 1892, when the Indiana fields

(a) From *The Mineral Resources of the United States, 1900.*

were being rapidly developed, both Ohio and Pennsylvania were producing large quantities of gas, and in order to secure the removal of manufactories to this territory, contracts at a very low price for long periods were made. In like manner, franchises for gas in Indiana cities were made which imposed conditions that were then easily complied with, but as the supply has diminished, are now very burdensome. The prices for manufacturing contracts were based on output, and for domestic consumption on the number of fires or size of openings in the burner instead of by meter. The average price of gas in this State is but little more than one-half the price of coal or wood displaced, while with equal economy its price should exceed coal owing to the greater convenience and cleanliness, a condition that is true for almost all other localities.

*Pennsylvania Gas Fields.*—Gas first began to attract attention as a fuel during the development of the Bradford and adjoining oil fields. In many sections in this region wells of high rock pressure and great volume were found and while the rock pressure now is, generally speaking, small, large quantities are still taken from McKean and the adjoining counties of Elk and Warren. However, before its value as a fuel was appreciated, the extensive fields about Pittsburg had been discovered. Among the first of these was at Murraysville, located 15 miles east of Pittsburg, a field of moderate depth, showing a loose sand, which yielded consequently a great volume of gas. The first well in this field, Haymaker No. 1, was opened November 4, 1878, in drilling for oil. No attempt was made to use the product of this well for four years, and very little drilling was done in the field until 1884. A short distance to the east of Murraysville was the Grapeville field, which though much smaller than the Murraysville field, contained wells of very large volume. Probably more gas was wasted from both these reservoirs than was ever utilized.

In the same month that Haymaker No. 1 was opened, the first well was struck near Tarentum, and as the supply from Murraysville and Grapeville diminished, this also was piped to Pittsburg, and as was needed, gas was brought from Canonsburg, Hickory and Venice, to the southwest. While the rock pressure is now very small in these various fields, and, while some of them have become entirely exhausted, they have showed wonderful lasting qualities. **Armstrong**

County has been producing gas for nearly 20 years and still yields a daily output approximating 50,000,000 cu. ft.

About 1890 the development of the territory south of Pittsburg began, although gas had already been discovered and used to considerable extent about Washington, Pa. Later the developments extended into Green and Fayette counties. At present the most prolific territory is in Green and Washington counties, where a "Bayard" sand pool was discovered in 1897. The sand lies about 300 ft. below the Gordon sand and 2,435 ft. below the Pittsburg coal. This pool has been explored from within a few miles of the West Virginia line northeastward to a point about five miles north of the Washington and Green county line. It is about 25 miles long, with a width of three or four miles. The rock pressure of the wells varied from 800 to 1,200 lb., and still shows from 400 to 1,000 lb., although the average daily output during the past two years cannot have been less than 75,000,000 cu. ft.

*West Virginia Gas Fields.*—In West Virginia the most prolific sands are the Gordon and those grouped near it, namely, the Gantz, Gordon Stray, Fourth, Fifth, and in some few places, the Elizabeth or Bayard sand; many large producers also have been secured from the shallower sands. Although vast quantities of gas have been taken from these reservoirs, they are the most extensive and prolific known at present. Vast areas of natural gas deposits exist in Wetzel, Marshall, Marion, Monongalia, Tyler, Harrison, Doddridge, Lewis, Ritchie, Gilmer and Calhoun counties, and many others farther south. Wells have been drilled which show rock pressures exceeding 1,200 lb. and volumes of from 12,000,000 to 20,000,000 cu. ft. per day, while some have been estimated as high as 50,000,000 cu. ft. If this supply is properly conserved, it will furnish vast quantities for many years, not only for local consumption, but for transportation to markets in Ohio and Pennsylvania which are now being supplied for the most part from the less distant fields. Unfortunately for the preservation of the gas, the deposits are almost invariably associated with oil pools, from which the gas is discharged with the oil, and in the past, little effort has been made to restrain its flow. From one region in Wetzel and Tyler counties, embracing 100 square miles, with an original rock pressure of about 1,000 lb., fully one-half of the entire supply has been wasted. It is a matter of regret that there is no satisfactory legal protection for this product. However the value of gas is now becoming so universally understood and the principal oil producers are either directly or indirectly interested in the gas companies, so that the former waste has very appreciably decreased and there is reason to believe a new era of economy in gas production and preservation has begun.

*Ohio Gas Fields.*—The chief supply of gas in this State, *i.e.*, the reservoir in the Trenton limestone, has been practically exhausted. This field originally embraced 500 or 600 square miles in the northwest portion of the State and had a uniform rock pressure of over 400 lb. At present the pressure is nearly exhausted, and the wells drowned out with salt water. In the eastern portion of the State quite a large quantity of gas was obtained from the Berea sandstone. However, the only source of any considerable supply at present known in the State is the Sugar Grove field south of Lancaster and the recently discovered

Licking County field to the north of it. The gas in these fields comes from wells in the Clinton limestone 2,000 ft. or more in depth and showed originally about 750 lb. pressure. The Sugar Grove field was first opened in 1887 and already shows no more than one-third of the original rock pressure. The amount of gas produced in Ohio reached its maximum in 1888 or 1889. From thence it steadily diminished until 1897, although later the production has increased considerably and the value of the product has nearly doubled. This increase in value has been due in a measure to a more economic method of handling resulting from an extensive adoption of the meter system of measurement. It seems probable however that the maximum production has about been reached and existing companies are making extensive preparations for securing large quantities of gas from West Virginia.

*Indiana Gas Fields.*—The productive area in this State originally extended over an area of between 2,500 and 3,000 square miles, located from the center of the State eastward and northward to the Ohio boundary. The source was from the Trenton limestone. Originally the fields showed a nearly uniform rock pressure of 325 lb., which now varies from zero to 150 lb. For the past nine years this State has produced more gas than any other, but the fields have become greatly depleted. Large compressing plants are installed to diminish the line pressure at the wells and to furnish power to transport the gas to points of consumption. It would seem that these more and more expensive methods of gas production must soon prevent the successful conduct of the gas industry in many portions of this territory unless relief is obtained from the uneconomic methods of consumption due to lack of meter measurement and a price obtained for the product more commensurate to its value.

#### THE ORIGIN OF NATURAL GAS.

Many theories of natural gas have been advanced, but the one which meets with most general acceptance is that propounded and discussed so ably by Prof. Edward Orton, in the *Geological Survey of Ohio*. Briefly stated, the theory is that gas and petroleum are the results of decomposition at moderate temperature of vegetable and animal matter, chiefly in the stratum where found. There seems to be little doubt expressed at present that its source is organic rather than inorganic, and while there are many adherents to the theory of distillation by heat, this latter theory is losing ground because, as a rule, there are no noticeable evidences of heat and furthermore it can be shown that a process of this character is unnecessary.

#### CAUSE OF ROCK PRESSURE.

Prof. Orton advocates that the pressure is hydrostatic, being due to the head of water which is entering the sands at the outcroppings or through breaks into other saturated layers, and showed in proof of this claim (1) that the pressure of the wells of the Trenton limestone agreed exactly with that which would result from a head at the level of Lake Erie, and (2) that water follows the gas into the rock as the gas is exhausted. However, Prof. I. C. White calls attention to the fact that at points in New York, Pennsylvania and West Virginia, the rock

pressure exceeds any possible artesian pressure, and further, the sands as depleted continue dry, which shows no evidence of communicating with water. In these cases, at least, it would seem that the pressure was due solely to the vast accumulations of gas.

### CHEMISTRY OF NATURAL GAS.

Natural gas is composed principally of the gaseous hydrocarbons of the paraffine group, whose general formula is  $C_nH_{2n+2}$ . Besides the paraffines, there are small but varying amounts of the following gases: nitrogen (N), carbonic acid gas ( $CO_2$ ), olefiant, oxygen (O), ammonia ( $NH_3$ ), hydrogen sulphide ( $H_2S$ ) and hydrogen (H). The paraffines however amount to 90 or 95% of the entire volume of the gas, and consist principally of marsh gas or methane ( $CH_4$ ). Frequently it is the only member of the series present. It seems difficult to separate the various members of this group, but the presence of the heavier members is frequently shown by the increased gravity, the increased heat units in its combustion and by the smaller proportion of water to carbonic acid gas in the products of combustion. The following table of the properties of the first three members of the paraffine group (the ones most frequently present) has been compiled from data in Schorlemmer's *Hand Book of Chemistry* and from the work of Prof. F. C. Phillips, which is published in the *Pennsylvania Geological Survey*, 1892.

PROPERTIES OF THE THREE LIGHTER MEMBERS OF THE PARAFFINE GROUP.

(a) B. T. U.—British Thermal Units or amount of heat necessary to raise one lb. of water at 89° F. through 1° F.

It is observed that the lower members of the series increase in specific gravity and in available heat units at a fairly constant ratio, each member yielding approximately 800 heat units to the cubic foot more than the one preceding. It should be observed also that the pressure on many natural gas reservoirs exceeds the liquefying pressure of the gas in all but the first member of the group. Consequently in such reservoirs all ethane and propane exist as a liquid, and are only vaporized at the bottom of the well as the pressure is reduced at that point. Since these gases are much richer in heat units than methane, it would seem probable that as the pressure of gas fields containing these liquids depletes a large proportion of them would vaporize and result in a richer gas being produced than in earlier stages of production. The next lower member, butane, of the series remains, in its normal state, a liquid at atmospheric pressure and 33° F. and consequently does not vaporize in large quantities under normal line pressure. The boiling points of the remaining members of the group are sufficiently high to preclude any large amount of their vapors being present in the gas.

Besides the paraffines, small quantities of the illuminants, or the olefiant series

( $C_nH_{2n}$ ), have been observed. About the only member of which an appreciable amount has been observed is ethylene ( $C_2H_4$ ). The analyses of gases from Trenton limestone in Ohio and Indiana as given in the *Geological Survey of* Vol. 6, page 137, show about 0.25% of olefiant.

The subjoined tables give a number of analyses of natural gas from various fields in New York, Pennsylvania, West Virginia, Ohio, and Indiana.

**Combustion.**—It will be observed that few attempts have been made to rate the hydrocarbons. The process is very difficult and unsatisfactory and chief and only use of gas is for fuel, the principal point to be considered heating power. (Its use as an illuminant is limited to the application of incandescent mantels, where the light is dependent on the heating power of gas.) This subject has been very carefully considered by many of the

chemists and physicists, notably Prof. C. C. Howard, in Ohio; Mr. Robert Young and Prof. F. C. Phillips, in Pennsylvania; Forrest M. Towl, and many others. The difference in their results are due mostly to differences in methods of analysis. For all practical purposes the following rule will give British Thermal Units (B. T. U.) per cubic foot: B. T. U.=per cent. of hydrocarbons  $\times$  specific gravity of gas  $\times$  18.3.

This formula is only a rough approximation, but gives a result slightly too small with gas of low specific gravity and correspondingly higher with the heaviest gases.

The products of the combustion of hydrocarbons vary in proportion to the amount of oxygen available for the combustion. If sufficient oxygen is supplied, the resultant products are steam ( $H_2O$ ) and carbonic acid gas ( $CO_2$ ). If the supply is insufficient, carbon is burned to carbon monoxide ( $CO$ ) with a loss of more than one-half of the heat units in the carbon. If the amount of oxygen is still less, the hydrogen will burn to steam and the carbon be deposited as soot, and in the last named case, nearly one-half of the heat units of the carbon will be lost.

To burn marsh gas in oxygen, the formula is:—

or 1 cu. ft. of marsh gas requires 2 cu. ft. of oxygen to burn it, the results produced being 1 cu. ft. of carbonic acid gas and 2 cu. ft. of steam.

To burn ethane, the chemical formula is:—

or 2 cu. ft. of ethane requires 7 cu. ft. of oxygen to consume it. Since the source of oxygen commonly used in combustion is the air, of which but 21% by volume is oxygen and 79% is innate nitrogen, about 5 cu. ft. of air is necessary to furnish 1 cu. ft. of oxygen, or approximately 10 parts by volume of air are necessary to burn one of methane and 17.5 parts to burn one of ethane.

As an example in combustion, suppose it is desired to burn gas under boilers or making steam, the composition of the gas being 95% paraffines, of which 25% ethane and 70% methane. Suppose the stack temperature to be 400° F. and the temperature of the air 60° F. There would be available in 1 cu. ft. of this gas,—

Methane, 70% of 1.064=744.8 B. T. U.

Ethane, 25% of 1.863=465.6 B. T. U.

Total, 1,210.4 B. T. U.

To burn this gas would require of air:—

70% of 10 cu. ft.=7 cu. ft.

25% of 17.5 cu. ft.=4.4 cu. ft.

Total, 11.4 cu. ft.

This would weigh  $11.4 \times 0.08071$  (weight of 1 cu. ft. of air)=0.92 lb. To this must be added the weight of 1 cu. ft. of the gas, or about 0.056, making 0.976 lb., or in addition to the work done in evaporating water in the boiler, each cubic

foot of gas must raise 0.976 lb. of the gaseous products of combustion from 60°F. to 400°F. or through 340°F. Since the average specific heat of the products of combustion is about 0.24, this work will consume

$$0.976 \times 0.24 \times 340 = 79.6 \text{ B. T. U.}$$

Subtracting this amount from the heat units in a cubic foot of the gas, we have  $1,210.4 - 79.6 = 1,130.8$  B. T. U. still available for evaporating water. If the temperature of the feed water be 80°F., it will take  $212 - 80 = 132$  B. T. U. to raise the temperature of 1 lb. of water to the boiling point and, since 965.7 B. T. U. are necessary to convert 1 lb. of water at 212°F. into steam of the same temperature, there will be necessary  $965.7 + 132 = 1,097.7$  B. T. U. to convert 1 lb. of water 80°F. into steam at 212°F., or the heat of 1 cu. ft. of gas would be sufficient to evaporate  $1,130.8 \div 1,097.7 = 1.03$  lb. of water from 80°F. to steam at 212°F. If the water was at 212°F. in the beginning, 1 cu. ft. of gas would convert  $1,130.8 \div 965.7 = 1.17$  lb.

Of course, in practice considerable heat is lost by radiation and other causes, and the above-mentioned conditions are not realized. However in a number of instances 1 lb. of water has been evaporated from a temperature of 212°F. for each cu. ft. of gas consumed. In December, 1900, at Tarport, Pa., 1 cu. ft. of gas with Klein burners evaporated 1.15 lb. of water under 80 H.P. boilers.

#### USES OF NATURAL GAS.

Natural gas is most valuable as a domestic fuel. For heating dwellings it is the ideal fuel, being perfectly clean, without dust or soot, operated without labor and with a thermostat connection for regulating the feed of gas by the temperature of the room it operates from week to week without attention and without any variation in the temperature of the apartment. For cooking it is unsurpassable. Besides being cleanly, it makes an extremely hot fire, is always at hand in a moment, and can be extinguished immediately when not needed. It permits the kitchen to be cool and clean, and with an over thermometer, the baking temperature can be controlled to a single degree. In roasting and broiling quick hot fire over the meat sears the outside and results in a sweeter, more juicy and heavier roast than is possible by any other means.

With reference to economy, natural gas at 25c. per 1,000 cu. ft. is as cheap for domestic heating and cooking as anthracite coal at \$5.50 per ton.

For manufacturing purposes it is probably most valuable in the manufacture of glass where its advantages are the reduction in labor in caring for furnaces; the improved quality of the product, due to the freedom from dust or soot to discolor it; and the longer life of the furnaces.

In the heating and melting of iron and steel, there is less wear on the furnace and smaller furnaces can be used for the same output than is possible with coal. It is economical and advantageous to use natural gas in annealing furnaces, for heating and welding furnaces, core ovens, heating furnaces where blasts are used and in all kinds of gas regenerating furnaces for heating and melting purposes.

In burning brick, a better color can be obtained and a better output from the

Ln because the fire is regulated more quickly and easily than with coal. In fact, tural gas is useful for nearly all purposes where coal may be used, except in e reduction of iron ore, where its composition and gaseous nature preclude its e.

Burned under boilers, with the most economic burners, natural gas at 10c. per ,000 ft. is about as economic as coal at \$1.20 per ton, even though the coal be urned in the most economic manner with mechanical stokers.

## NICKEL AND COBALT.

As in previous years the domestic production of nickel and of cobalt oxide in the United States has been derived as by-products from the treatment of ~~le~~ ores at Mine La Motte, Mo. The production of metallic nickel from domestic ores in 1901 amounted to 6,700 lb., as compared with 9,715 lb. in 1900, showing a decrease of 3,015 lb.; while the production of cobalt oxide in 1901 was 13,360 lb., against 12,270 lb. in 1900, an increase of 1,090 lb. There has been considerable prospecting for nickel ores in many widely separated localities in the United States, and while exploitation has been active, no production of nickel ores on a commercial scale resulted during 1901. Development work has been carried on with more or less promise at the following localities:—

*Arizona.*—In Pima County a new deposit of nickel ore is being exploited.

*Idaho.*—At St. Joe mine, Blackbird, an arsenical pyritic mineral was reported, samples of which assayed as high as 8% nickel.

*Nevada.*—At Lovelocks Station, operating in the deposits of nickel and cobalt arsenides; at Bunkerville, operating in deposits similar to the Sudbury (Ontario) ores, and near Candelaria a deposit of nickel ore has been reported.

*North Carolina.*—Near Morgantown, in the western part of the State, deposit of nickel ore somewhat similar to the New Caledonia ore is being opened up.

*Oregon.*—A high-grade cobalt ore deposit is being developed in the eastern part of the State.

*Wyoming.*—At Piney Creek, in the northern portion of the State, the occurrence of nickel ore has been noted.

(a) The nickel reported as in oxide is now mostly converted into metal before consumption. (b) Includes nickel, nickel oxide, and alloys of any kind in which nickel is the chief element of value, but not manufactures, ore, or matte. (c) Ore and matte. (d) Comprises domestic nickel, nickel oxide, and matte.

*Market.*—The demand for nickel in the early part of 1901 was brisk and heavy purchases were made; the consumption, however, was disappointing, and at the end of the year consumers had considerable stock on hand. Trade was brisk and the price was steady throughout the year, ranging from 50 to 60c. per lb., depending on the size of the order. In this connection it should be noted that by far the greater part of the output is sold at private sale at an average price much lower than that reported as the market price.

UNITED STATES PRODUCTION AND IMPORTS OF COBALT OXIDE.

| Year.     | Production | Imports. |          | Year.     | Production | Imports. |          |

| 1897..... | 19,300     | 24,771   | 24,773   | 1900..... | 12,270     | 54,073   | 88,651   |
| 1898..... | 9,640      | 23,731   | 49,245   | 1901..... | 13,360     | 71,999   | 124,308  |

A very important step in the development of the nickel industry was made early in April, 1902, by the organization, under the laws of New Jersey, of the International Nickel Co., which resulted from plans to consolidate and control the nickel production of the world. The capitalization of the International Nickel Co. consists of \$12,000,000 common stock, \$12,000,000 preferred stock carrying 6% dividends non-accumulative, and \$12,000,000 of 30-year 5% gold bonds. Of this total capital, \$9,000,000 of common stock, \$9,000,000 of preferred stock, and \$10,000,000 of bonds was issued for the purchase of the following properties in the United States, Canada, and New Caledonia: The Canadian Copper Co.; the Orford Copper Co., with reduction works at Bayonne, N. J.; the Anglo-American Iron Co. and the Vermillion Mining Co., in Canada; the American Nickel Works, in Camden, N. J.; the Nickel Corporation, Ltd., and the Société Minière Caledonienne, in New Caledonia. The Société le Nickel, owning extensive properties in New Caledonia and a reduction plant in France, is not included in the combination, although it is believed that an understanding exists between them which will regulate the production and price of nickel, together with the apportionment of the trade. Other companies owning properties in the Sudbury district, Canada, not in the combination, are: The Mond Nickel Co., with a refining plant in England; the Lake Superior Power Co., with a refinery in course of construction at Sault Ste. Marie, and the Nickel Copper Co., of Ontario, with a refining plant at Hamilton. The extended use of nickel steel explains the interest in the International Nickel Co., taken by the United States Steel Corporation, although no official connection exists between the two companies.

In Germany the firm of Basse & Selve produces nickel from Norwegian and New Caledonian ores and occasionally from copper matte. In addition to this firm there are one or two nickel refineries of lesser importance. The International Nickel Co. and the Société le Nickel will control in the near future by far the greater part of the production of metallic nickel in the world.

*Austria.*—The production of the Martha and Benno nickel mines in the district of Frankenstein, Silesia, has risen very rapidly from 80 tons of nickel ore in 1899 to 3,896 in 1900, and it is estimated that the 1901 production is much

by the legislature of Ontario, amending the Mines Act (Chapter 100) providing for an export duty as follows:—

\$25 per ton, or \$25 per ton of metal contents if partly of nickel, \$10 per ton, or \$60 per ton of nickel contained; for ores of copper and nickel, \$7 per ton, or \$7 per ton of metal contents of copper and nickel.

tion by the Lieutenant-Governor before be-

of copper-nickel matte, which was produced in 1901 was refined in the United States, containing 4,768 short tons of matte. The refining of copper-nickel matte has not been done before, however, experiments have been made and others have not been made, the fact, coupled with the active and the active proposed legislation

In 1901 the operations of the Victoria mine were due to the efforts of one company, the same as the previous one, but with the completion of the mine in May, 1901, and the successful operation from 150 to 200 tons of ore per day since that time a new and massive epoch has been initiated. The Victoria mine has been exploited systematically to the fifth level in solid rock on one side of the main deposit a large independent body of ore has been found. The ores average 3% Ni and 3% Cu, a content well above the paying point. Another property belonging to the same company is in the township of Garson, 9 miles to the northeast of Sudbury, but is but little developed for lack of railway facilities.

The Lake Superior Power Co., of Sault Ste. Marie, has been opening the Gertrude mine, at Creighton, for a number of years, although but a few carloads have been shipped for experimental purposes. In 1901 the company purchased the Elsie mine, at McKim, and the Jarvis mine, near Lake Wahnapiatae, all containing high-grade nickel ore. The Gertrude and the Elsie mines have contributed about 15,000 tons of ore to the roast heaps during the past year. Most of the output of these mines will be converted into matte at the three-furnace smelting plant which will be erected during 1902, near the Gertrude mine, instead of shipping to Sault Ste. Marie, as was at first intended. In the building of the first section of the Manitoulin & North Shore Railway from Sudbury to the Gertrude mine the Lake Superior Power Co. has accomplished an exceptional improvement of the Sudbury district; the first section, while but 13 miles in length, passes close to six good mines, one of them containing the largest ore body of the district, and although but three of these mines were operated during

(a) Individual statistics not yet reported. (b) Nickel in ore and matte, nearly all the Canadian nickel is refined in the United States. (c) Nickel in Norwegian ore, included in U. S. production from imported ore. (d) Statistics not available.

NOTE.—The figures for France and Prussia are from official reports; the amount credited to England has been obtained by deducting the output in France from the combined output of the French and English works as given by the *Metallurgische Gesellschaft, A. G.*, except in 1899, when the English production was reported separately. The actual output of all English works is somewhat greater than the above amounts as a little Canadian ore is smelted there. The Prussian figures include a small amount of nickel of domestic origin. The Canadian figures are those of the Geological Survey of the Dominion. The world's total has been arrived at by adding the production from New Caledonian ores, the output of Canada and Norway, and the domestic production of the United States. In 1899, however, the total represents the total output in the United States and the production from New Caledonia ores, since the imports into this country were not derived from Canada alone.

larger. Late in 1900 a Robert-Stollen smelting furnace with a daily capacity of 25 tons was erected and in operation during the year.

*Canada.*—According to the report of the Dominion Geological Survey, the production of nickel in Ontario in 1901 was 9,189,047 lb., valued at \$1,859,970, against 7,080,227 lb., valued at \$3,327,707 in 1900. The detailed statistics of Ontario, compiled by A. Blue, Esq., director of the Ontario Bureau of Mines, are as follows:—

| Schedule.                         | 1896.     | 1897.     | 1898.     | 1899.     | 1900.     | 1901.       |

In connection with the development of the nickel industry in Canada there was considerable agitation in Parliament during 1901 over the proposed Acts affecting the levy of an export duty on the copper nickel products of Ontario. These Acts, though passed by their respective parliaments, are not yet operative, as the necessary proclamations have been withheld awaiting the decision of the Supreme Court of the Dominion of Canada, to which the matter has been referred on appeal. The Acts referred to are:—

1. That passed by the Dominion of Canada (Chapter 17 of 60-61 Victoria) giving the Governor-General power to levy an export tax on copper nickel products of Ontario. The export duty, as passed by Parliament, is as follows:—

“On nickel contained in matte or in the ore or in any crude or partially manufactured state, and upon copper contained in any matte or ore which also contains nickel, when exported from Canada, upon such nickel an export duty not exceeding 10c. per lb., and upon such copper an export duty not exceeding 2c. per lb.”

2. That passed by the legislature of Ontario, amending the Mines Act (Chapter 13 of 63 Victoria) providing for an export duty as follows:—

“For ores of copper, \$2 per ton, or \$25 per ton of metal contents if partly treated or reduced; for ores of nickel, \$10 per ton, or \$60 per ton of nickel contents if partly treated or reduced; for ores of copper and nickel, \$7 per ton, or \$20 and \$50, respectively, per ton of metal contents of copper and nickel if partly treated or reduced.”

These duties require a proclamation by the Lieutenant-Governor before becoming operative.

With the exception of 1,147 short tons of copper-nickel matte, which was produced by the Mond Nickel Co., at Victoria mines and shipped to England, the entire Canadian production of matte during 1901 was refined in the United States, which amounted to 58,364 short tons, containing 4,768 short tons of metallic nickel. It was with a view to develop the refining of copper-nickel matte in Canada that the Acts of Parliament were made. Heretofore, however, experiments conducted to this end by the Canadian Copper Co. and others have not resulted satisfactorily from a financial standpoint, and this fact, coupled with the shipment of nickel ores from New Caledonia and Norway and the active exploration of nickel fields in the United States, renders the proposed legislation of doubtful value to Canadian interests.

(By A. McCharles.)—For several years before 1901 the operations of the nickel mines of the Sudbury district were confined to the efforts of one company, the output each season varying little from the previous one, but with the completion of the Mond Nickel Co.'s plant in May, 1901, and the successful operation of its plant at the rate of from 150 to 200 tons of ore per day since that time, a new and more progressive epoch has been initiated. The Victoria mine of this company has been exploited systematically to the fifth level in solid massive ore, and to one side of the main deposit a large independent body of similar ore has been found. The ores average 3% Ni and 3% Cu, a content considerably above the paying point. Another property belonging to the same company is in the township of Garson, 9 miles to the northeast of Sudbury, which is but little developed for lack of railway facilities.

The Lake Superior Power Co., of Sault Ste. Marie, has been opening the Gertrude mine, at Creighton, for a number of years, although but a few carloads have been shipped for experimental purposes. In 1901 the company purchased the Elsie mine, at McKim, and the Jarvis mine, near Lake Wahnapiatae, all containing high-grade nickel ore. The Gertrude and the Elsie mines have contributed about 15,000 tons of ore to the roast heaps during the past year. Most of the output of these mines will be converted into matte at the three-furnace smelting plant which will be erected during 1902, near the Gertrude mine, instead of shipping to Sault Ste. Marie, as was at first intended. In the building of the first section of the Manitoulin & North Shore Railway from Sudbury to the Gertrude mine the Lake Superior Power Co. has accomplished an exceptional improvement of the Sudbury district; the first section, while but 13 miles in length, passes close to six good mines, one of them containing the largest ore body of the district, and although but three of these mines were operated during

1901, the road is said to have paid well during the year. Eventually the road will traverse the entire nickel range almost from end to end.

The last year of the independent existence of the Canadian Copper Co. was the busiest of its 15 years of history. The capacity of the smelting plant was almost doubled during the year, but owing to the opening of the Creighton mine, undoubtedly the greatest deposit of nickel-copper ore in the district, the smelter was unable to treat all the ore available.

The mining operations of the Nickel-Copper Co., of Hamilton, have come to an unfortunate end owing to the complete failure of the new self-roasting process-plant erected at Worthington Station.

*New Caledonia.*—The Société le Nickel during the latter part of 1901 started the erection of a new blast furnace plant at Thio, on Mission Bay, but made little progress owing to trouble with the imported Japanese laborers. During the year some work was done on the nickel mines of the Canala district, and a little development was also accomplished on the cobalt mines of Bogotha Peninsula. Early in 1902 considerable development work was initiated in the Thio district. Messrs. Bardey & Roland purchased the Prise de l'Alma, and the Prise de Riva mines, near Port Bouquet, which will be actively worked during the year. M. Bruthiaux has begun work on the Puy-de-Dome mine at Kuakue, and a tramway 3 km. in length is under construction to convey ore from the mines to Port Bouquet. The exports of nickel ore from New Caledonia in 1901 were 133,098 metric tons, as against 100,318 metric tons in 1900, while exports of cobalt ore were 2,872 and 2,437 metric tons, respectively. Smelting and refining works for the New Caledonia ores were erected at New Castle, New South Wales, and extensive beds of nickel ore are reported to have been discovered in the colony of New South Wales.

(By F. Danvers Power.)—The only nickel ore that occurs in New Caledonia is the hydrated silicate of nickel, free from sulphur, arsenic or copper, in which more or less of the nickel oxide is replaced by magnesia, ferric oxide and alumina. Mr. T. Moore, of Noumea, gives this mineral the formula  $7\text{NiO} \cdot 6\text{SiO}_2 + \text{H}_2\text{O}$ . The mineral occurs in two forms: the usual green noumeaite, which is classed in works on mineralogy as amorphous, but acicular and blade-like crystals of which have been found at Dumbea; and the "chocolate nickel," which looks, both in color and grain, like cake chocolate, hence the name. The green ore, which when pure contains from 45 to 48% NiO, merges into the brown, which in the pure state carries 43.5 to 46% NiO. At first the "green nickel" was mistaken for copper carbonate, while the "brown nickel" was thrown away as worthless earth. The darker the mineral, whether green or brown, the richer it is in nickel. The noumeaite was evidently deposited from solution, and that mostly from above, for the ore bodies are superficial, while the mammillated and stalactitic structures tell their own tale. The nickel ore contains a little cobalt, seldom over 0.6% CoO. There was a reported find of nickel sulphide at Bourail some two years ago, and Mr. Moore had some small chips of yellowish nickel sulphide brought to him for determination, but on a careful personal investigation of the workings alleged to have furnished the samples submitted, I failed to find any trace of a sulphide of any kind, though the workings were not extensive, and were

still quite fresh. The minerals associated with these nickel ores, beside those constituting the rock, are chromite and asbolite in small quantities.

The nickel deposits are found between 400 and 4,000 ft. above the level of the sea, generally about 2,000 ft., the country rock being peridotite. The hills and valleys appear to have been mostly formed by anticlinal and synclinal curves, the latter having been deepened by river erosion, for the country is very well watered. Where cuttings intersect spurs that are not too much broken up by landslips, one can almost always see an anticlinal structure, the bands into which the peridotite is divided giving it almost a bedded appearance. The mountains are very steep and do not as a rule have much soil on them; what there is being very ferruginous and supporting but a scanty vegetation. The steepness of the mountains has helped in the formation of landslips, which are indicated by the profile of the spurs. This is interesting as certain of the landslips that have broken up the rock to the necessary degree are the sites of the most important nickel deposits, while the physical appearance of the surface acts as a guide to the prospector. In some places the ore crops out at the surface, at others it is covered with red earth in which pisolitic iron is found. In the latter case one may walk over the ground several times without finding any trace of nickel. The nickel is often leached out of the deposit at the surface, to be concentrated a few feet lower down. Pisolitic iron and a network of quartz veinlets are considered favorable signs for nickel deposits. What they really indicate is that the rock has been more or less broken up and decomposed, and therefore it is likely that the nickel originally in the rock has been concentrated in their neighborhood, though perhaps not showing on the surface. When the peridotite is decomposed under ordinary conditions, the magnesia appears to be the first ingredient to be carried away, in the form of carbonate; this is followed by nickel and quartz, which are deposited in the joints; the iron becomes oxidized and hydrated, and coming in contact with scarcely any solvent capable of acting on it, remains behind; furthermore, as it is heavy, when rains wash away the earth in which it is imbedded, the pieces of iron ore become concentrated on the surface. It is interesting to note that fresh undecomposed pieces of peridotite, consisting chiefly of olivine, contain nickel up to 1%, from which the occurrence of an extensive deposit would appear to prove that either there had been a large quantity of rock above it, now disintegrated, or else that the nickel had leached out from the higher lying ground. The deposits may be divided into two classes: (1) Those in which the ore is found in joints and slides in hard rock, and (2) those in which the rock is more or less decomposed, so that it has to be worked out in bulk. There can be no sharp division of the two classes unless extreme types are taken, though they undoubtedly exist with reference to origin, and decidedly affect the mining of the deposits.

In the former case (1) the joints are filled with rich green nickel that can be picked out from the rock which, for commercial purposes, is barren. Being rich, the expense of considerable dead work can be borne for the sake of the small quantity of ore won. This kind of stockwork is generally caused by the sharp bending of the rock, which causes tension joints to form without breaking the rock between into small pieces. The walls of the joints may be weathered

for an inch or two and this being nickel bearing, is "knapped" off. There are also fault planes 3 or 4 ft. wide, filled with rubbed up pieces of country rock cemented together with green nickel. These cementations were worked in the early days of nickel mining in New Caledonia when only the richest ore paid for its extraction.

At the present time the decomposed deposits (2) produce the greater bulk of the ore. It is mostly brown ore, and is poorer than the green nickel on account of being contaminated with so much decomposed rock. It generally accompanies a landslide which, in sliding down in a body, breaks up the ground in such manner as to enable the rock to be readily weathered. There is a considerable green nickel in these deposits which evidently occupied the joints before the rock was so completely decomposed; possibly some of it was formed before the mass slipped down, when it may have constituted the harder deposit. Occasionally a hard bar of rock is found which for some reason has withstood the weathering action better than the rock surrounding it. It could not be determined whether the nickel was limited to any particular variety of peridotite, but it occurs more frequently in the more common sorts, probably because there was more of it rather than on account of any slight difference in the proportion of its mine constituents. Sometimes these deposits end rather suddenly against rock, while at other times they get poorer gradually. They vary in size from 6 in. to 30 in. in vertical depth. These differences may be due to the varying effects of weathering action on the rocks under different physical conditions, but very likely the shallow deposits are merely the remnants of larger ones, the bulk of which has been washed down the hillsides. Without considering any leached surface stone that may have to be removed, the part of the deposit nearest the surface is the richest portion, getting poorer as it enters the hill; the higher part of the deposit is also richer than the lower, as if only the dregs of the nickel in solution escaped precipitation higher up and near the surface and found their way lower down the hill. Still, though the deposits are comparatively shallow they cover large areas and there are deposits working now that have already produced from 30,000 to 100,000 tons of ore, which have every prospect of yielding as much again.

The method of mining is simple open cut work; the ore is taken out in benches having faces about 30 ft. high. The ore, after being blended to a shipping grade, is sent to the low land on aerial ropeways and then conveyed to the coast by ground trams, from which it is transferred to lighters for conveyance to ships.

*Chile.*—During the latter part of 1901 shipments of cobalt ores were made from Caldera to the United Kingdom, and it is anticipated that the return will show sufficient profit to render the re-opening of the mines advisable.

*Mexico.*—In the Mirador mine, in the State of Jalisco, an unusual occurrence of cobalt ore was discovered during 1901. The rock is a blue quartz, very hard and tough, showing some minute specks of pyrite. The analyses showed 98% SiO<sub>2</sub> from 0.42 to 0.55% Co, and from 0.40 to 0.50% Fe. The cobalt and iron are combined with sulphur, but apparently not associated with each other. Neither nickel nor copper could be determined in the ore.

*Norway.*—Experiments made on Norwegian nickel ores at Soetersdalen,

the Osteröen works, near Bergen, and at the Foeö works near Hangesund, during the latter part of 1900, were successful, but little or nothing has been done to open the deposits owing to the lack of capital for the opening of the mines on a practical working scale.

*Russia.*—During the latter part of 1901 the discovery of rich deposits of white nickel and asbestos was reported from the neighborhood of Zanghésour, Province of Elizabethpol.

#### THE COBALT ORES OF NEW CALEDONIA.

BY F. DANVERS POWER.

THE cobalt ore occurring in New Caledonia is cobaltiferous manganese oxide, and the output for 1901 amounted to 3,123 metric tons, as compared with 2,437 tons in 1900. Cobalt ores are generally found associated with nickel ores, but independent of the nickel deposits, though the cobalt ore carries from 1 to 2% NiO, and nickel ore from 0.1 to 0.2% CoO. The cobalt deposits are purely superficial and are mostly found on the mountains in a reddish earth formed by the decomposition of the peridotite. Miners seek for dark stains of manganese oxide, locally called "cobalt smoke," and depend on these to lead to something more tangible, or if they are in a cobalt district, they burrow at random into the earth in the hope of striking a body of ore. The peridotite has a band-like structure, which has become buckled into anticlinal and synclinal curves. The cobaltiferous manganese (probably obtained from the original rock, the residue of which now forms the large bodies of red earth) concentrated in the joints, especially those of the bed-like type, and in the parts that form the synclinal. These main joints are followed by the miners until too small to be profitable. The cobalt ore was evidently deposited in the joints before the rock was completely decomposed, for the ore can be traced in the joints from the slightly decomposed rock into red earth, and also into the rock structure until it is obliterated by the apparently uniform mass of earth. When two or more joints meet, a pocket of ore may occur. The cobalt ore in the solid rock can be picked out by hand, but in the red earth it is often broken up, and so mixed with worthless material that it requires to be cleaned by weathering and washing. The red earth being soft is readily washed away by rain and small streams of water, and the prospector is aided in his work by exposing the deposits to atmospheric agencies, preferably driving a tunnel rather than sinking a shaft.

The mining is generally carried out in a very primitive and erratic manner, but the principle on which the larger mines are worked is to follow a more or less horizontal body of cobaltiferous manganese into a hill by means of a tunnel as far as it will pay; about every 30 ft. in distance branch drives are put in at right angles to the main one, in order to discover the lateral payable limits of the ore. When these are found the ore is blocked out from the far end and the ground allowed to fall in behind. The drives are most irregular in direction and grade and there seems to be no systematic prospecting done to determine how many veins of ore there are to be mined and the best way to win them at the least possible loss.

The dressed cobalt ores, which assay from 3 to 8% CoO, are blended to form

the shipping grade of from 4.75 to 5% CoO. The cleansing of the ore also is very primitive. In the mine the ore is kept as clean as possible from the earth, but there is always a certain proportion that cannot be separated by hand picking. Ore of this character is sometimes allowed to weather for a few days and is then sent down in bags to a creek, where it is crushed by hand with a big wooden pestle and washed in a sluice box by shoveling the material against the down-flowing stream of water. In this way the ore as mined is concentrated from 3 to 9 parts into 1.

It is interesting to note that the cobalt ore at Port Macquarie, in New South Wales, is of a similar nature to the deposits in New Caledonia—the ore occurs in the joints of altered peridotite and serpentine, more especially in the trough folds. At Port Macquarie, however, there is less red earth than in New Caledonia and the deposits are not at so high an elevation above the sea level.

#### PROGRESS IN THE METALLURGY OF NICKEL DURING 1901.

BY TITUS ULKE.

*The Lake Superior Power Co.*—This company has completed the first set of 16 Herreshoff roasting furnaces at Sault Ste. Marie, with which it is proposed to roast dead 50 tons per day of finely crushed ore from Sudbury mines, and pyrites from Michipicoten. The furnaces are fired by producer gas and the sulphurous acid gas produced is utilized for the treatment of wood pulp by the sulphite process and for making liquid sulphurous acid. At present the roasted ore is briquetted in a Boyd & White press and stored for future use. It has been proposed to manufacture ferronickel from the roasted ore, but its copper content is believed to be too high for this purpose. The company has blown in one and is erecting two more elliptical water-jacketed furnaces near its Gertrude mine on the Manitoulin & North Shore Railroad for treating the heap-roasted nickel-copper ore from the Elise and Gertrude mines. Two stands each of three trough converters, furnished by Fraser & Chalmers, are to be placed on the terrace below the smelting furnaces for converting the daily output of about 40 tons of nickel-copper matte.

The Lake Superior Power Co.'s method of handling ore to and from the roast-heaps by locomotive, side-dumping cars and steam-shovel is excellent, and is far more economical than the prevailing method of hand-wheeling and shoveling adopted by the Canadian Copper and Orford companies.

*The Canadian Copper Co.*—Among the improvements introduced at the smelting works of the Canadian Copper Co., at Copper Cliff, is the efficient flue-dust chambers with which the new water-jacketed elliptical furnaces are supplied. It has also been profitable to replace a certain proportion of the roasted charge in smelting by "green" (i.e., unroasted) ore, although a low-grade matte is thereby produced. The Canadian Copper Co. operates about 80 roast-heaps and 9 furnaces which smelt approximately 900 tons of ore per day. Twelve hundred men are employed at an average wage of nearly \$2 per day. The ores average about 2% Cu and 2% Ni, although the Creighton mine supplies ore that averages about 5% Ni and quite low in copper. The cost of roasting at Sudbury has been estimated not to exceed 17c. per ton of ore and the cost per pound of nickel con-

tained in the matte lies between 7.2 and 7.8c. At the beginning of the year 1902, the average composition of the matte produced by the Canadian Copper Co. was about 13.2% Cu, 17.8% Ni, 0.45% Co (=2.5% of the nickel present), 42.0% Fe and 21.4% S. Besides these elements it contains about 1.90 oz. silver, 0.35 oz. platinum and 0.35 oz. palladium per ton, or a total value per ton in precious metals of about \$13.50. The slag produced at Sudbury varies between 27% and

FIG. 1.—THE WORKS OF THE CANADIAN COPPER CO., AT COPPER CLIFF.

38%  $\text{SiO}_2$ , 43 and 46%  $\text{FeO}$ , and contains about 4.5%  $\text{CaO}$ , 2.5%  $\text{MgO}$ , 10.0%  $\text{Al}_2\text{O}_3$ , 2.0% S, 0.3 to 0.4% Cu and 0.3 to 0.4% Ni.

*The Ludwig Mond Co.*—The plant of the Ludwig Mond Co., at Victoria, 22 miles west of Sudbury, was completed early in the year and smelting commenced in May, 1901. The nickel and copper ores are heap-roasted, smelted to matte and Bessemerized to a metallic content of 80% nickel and copper. The ore mined by this company in 1901 amounted to 46,807 short tons, of which 18,628 tons were smelted and produced 1,147 tons of matte containing 462 tons of copper and 455 tons of nickel. This matte was shipped to England. Since beginning operations

the type of the charging thimble has been reduced to 18 in., which permits of a better distribution of the charge in feeding the furnace. The walls of the settler have been increased in thickness to the extent of an additional width of fire brick, which has resulted in prolonging the life of the settler. The granulation of the matte has been discarded on account of the difficulty encountered from the numerous violent explosions. The following charges were recently made to the furnace: From 1,500 to 1,800 lb. roasted ore, from 400 to 750 lb. of low-grade siliceous ores, called "rock," and from 0 to 600 lb. converter slag. Each charge weighed about 2,500 lb. and required 300 lb. of coke for its reduction. Occasionally green ore is added and at times a portion of the matte is resmelted. During 24 hours the converters produced 44 plates, or 11 tons of 80% matte, which is a very large output considering that only one matting furnace under a blast pressure of 3 oz. was in commission. This furnace treated 150 tons of material in 24 hours, an amount which could be easily increased by raising the blast pressure. The blast is preheated by leading the air from the blowers into a passage way, built above the dust flue and separated from it by a steel diaphragm, thus utilizing the heat of the waste furnace gases. The air enters near the chimney to which the flue leads and proceeds toward the furnaces where the furnace gases have the highest temperature. The dust flue is constructed of steel plates lined with fire brick and is 160 ft. long, 9.5 ft. wide and 11 ft. high, including the air passage way, which is 24 in. high at its center. (See Fig. 1.) The weight of the flue in the smelter building is carried by the steel beams of the charging floor. It is estimated that from 400 to 500 tons of ore can be smelted daily in two 44×120 in. water-jacketed copper furnaces. Each furnace is provided with 8 tuyeres on a side, placed 15 in. between centers, and with a steel water jacket 8 ft. in height. A 6-in. water space is allowed between the inner and the outer walls of the jackets, which are of 0.375 in. and 0.3125 in. thickness, respectively. The side jackets are 5 ft. wide and the end jackets 4 ft. wide. The furnace is 18.5 ft. in height from the ground to the charging floor and the charging opening is 7×2 ft. in size. The centers of the tuyeres are on a level 5 ft. 8 in. above the floor. The crucible is 22 in. in height from base plate to water jacket and is supported on a thick iron plate resting on 12 cast-iron columns 3 ft. 1 in. in height. Above the jackets, vertical brick walls 9 in. thick are carried a distance of 5 ft. 3 in. to the charging floor. The inner dimensions of the furnace at the tuyere level are 3 ft. 8 in.×10 ft. and at the top of the jacket, 5 ft. 8 in.×10 ft. The slag and matte produced in these furnaces are run into a settler or forehearth and there separated by gravity and periodically tapped. The forehearth is 9 ft. in outside diameter and 3 ft. 6 in. in height. It is supported on 45-lb. rails, riveted to the bottom, the rails resting on rollers 2 in. in diameter and 2 ft. 6 in. long, so that the top of the fore-hearth is 4 ft. above the floor level. The lining is enclosed in a shell of tank steel 0.1875 in. thick at the sides, and 0.25 in. thick at the bottom, respectively, stiffened by 2.5×2.5×0.5 in. angles. To the half covers of the forehearth are riveted 30-lb. rails and 3×3×0.5 in. angles, two lifting handles being attached to the latter. The forehearth has a copper spout and a copper tapping jacket 2 ft. wide by 2 ft. high and 4 in. thick at the tap hole, containing several sections of 1-in.

wrought iron pipe cast in the piece. A guide 18 in. wide and 11.5 in. high is bolted to the forehearth and supports the copper spout which is 13 in. long, 6 in. wide, 4.5 in. high and 1 in. thick, with a flange 11.75 in. wide and 8 in. high. At present the slag flowing from the settler is wheeled to the dump and poured, but eventually it may be granulated and carried to a pit, from which it can easily be lifted by an endless chain and buckets to a bin and loaded in the cars. The matte accumulating in the settlers is periodically tapped into movable launders and run into the two 6-ton converters. The plant is equipped with six converter shells and two stands. The converters are of the horizontal type and measure 6 ft. 8 in. in diameter and 7 ft. in length. They rest on roller wheels supported by a strong cast-iron frame and are revolved by a vertical rack bar extended downward into an hydraulic cylinder and geared with a toothed wheel attached to the converter. The wind-box, 6 ft. long and 1 ft. high, is bolted to the converter and supplies the blast through 11 tuyeres on one level. The Bessemerized matte from nickeliferous copper is poured into a ladle suspended from an overhead traveling crane and is cast direct into plates. Ordinary clay from the neighborhood of the plant is used as a binder with the crushed quartz for lining the converter. The newly lined converters are dried by burning a few sticks of wood with a slight blast inside. The converting of the nickel-copper matte is now carried on as follows: The ordinary matte, averaging between 30 and 50% Ni+Cu and varying in composition with the grade of the material fed to the smelting furnace, is tapped from the settler and run into the converter so as to fill it nearly to the level of the spout in the charging position. During the next 30 to 45 minutes the tuyeres are occasionally opened by inserting a cleaning bar, and finally the converter is tilted and the first slag skimmed. As soon as matte begins to show, (determined by peculiar spots appearing on an iron rod held in the slag stream) the converter is turned up and the second stage of converting commences, which usually lasts about 40 minutes. During this time the iron is almost completely removed and a few additional pots of slag may be skimmed off. The operation is continued until the slag foams or becomes granular and the proper finishing flame appears, accompanied by the right "action of the converter," as determined by the man in charge. The Bessemerized matte, if sufficient in quantity, is then poured into a ladle suspended from a traveling crane to be cast into shallow plates, or, if small in amount, it is allowed to remain in the converter, and an additional quantity of ordinary matte is tapped from the settler and run into the converter, and the operation repeated. In this manner two or three tapplings of ordinary matte are run into the converter before the charge is finished and enough Bessemerized matte accumulated to make nine or ten plates, each weighing about 500 lb. In these cases three to four hours may elapse between the first charging of the converter and pouring of the finished matte. Occasionally it is necessary to transfer the charge from one converter to another because of the dangerous thinning down or burning through of the converter lining. The converters are said to stand from 4 to 8 charges of matte before they require complete relining.

According to Mr. Paris, of the Mond Co., a typical analysis of the granulated converter slag was  $\text{SiO}_2$ , 49%; Cu, 4%; Ni, 18.6%; and Fe, 16.9%. Ordi-

nary converter slag averages about 1.5% Cu and from 1.5 to 2% Ni, and is returned to the blast furnace feed-floor to be added to the smelting charge. For good practice the converter hoods should be built 18 in. higher than those in the Mond works, in order to restrict the spattering of portions of the charge; and each of the rails attached to the converter body should be in two sections instead of one, the joint being placed for greater convenience in handling at the junction of the hood and the converter body.

The composition of the Bessemerized matte produced at Victoria is about as follows: Ni, 37.78%; Cu, 41.4%; Fe, 0.65%; S, 18.37%; and  $\text{SiO}_2$ , 0.19%.

*The Orford Copper Co.*—During 1900 the Orford Copper Co. erected a plant at Copper Cliff to treat the nickel-copper matte furnished by the Canadian Copper Co. The matte is roasted in Brown straight-line calciners and smelted in an Orford cupola furnace to a matte containing 80% of Ni+Cu, which is shipped to the Orford works for treatment. The following description of the new plant was kindly furnished by Mr. J. A. Robert: The equipment consists of a 75-H.P. engine, two 125-H.P. boilers, dynamo, Cameron pump, Krupp ball mill, Blake crusher, two Brown straight-line calcining furnaces and two cupola smelting furnaces as outlined in the plan given in Fig. 1. The copper-nickel matte is at *B*; thence through a spout to the 50-ton Krupp mill at *C*, after which it falls delivered from cars at *A* and fed to the hopper of the 16×20 in. Blake crusher to the floor at *D*. At present the fine material is taken in barrels to the hoppers of the calciners *EE*, but later it is intended to use a conveyor to carry this material to storage bins located above the hoppers. The calcining furnaces are fed automatically and each treats 40 tons per day. The roasted matte containing from 8 to 10% S is received at the end of the roasting furnace in a screw conveyor *V* and is spouted to the boot of the bucket elevator *L* and lifted to the bins *O* of the two Orford smelting furnaces *QQ*, adjacent to the bins for ore and coke. In front of the bins are two small platform scales *PP* for weighing the charges. There are two boilers at *T* and an engine house *U* with two Sturtevant blowers to furnish blast for the furnaces. A small electric plant *Z* will supply arc light to light the works with and will furnish current for use in the laboratory. *W* and *X* are railroad tracks for handling material to and from the works. Coal is received in bins at *V* and falls by gravity through a door at *M* in front of the fireboxes *NNN* of the calciners *EE*. The carpenter shop, blacksmith shop and storehouses are located along the track *X* on the lower level. The office, laboratory, drafting room and club house are on the higher levels near the works. Each Orford furnace is of 100 tons daily capacity, and the dust flues *RR*, one over the other, lead from the furnace to the stack *S*. It is intended to produce a finished matte of 80% Ni+Cu which will be received from the spout of the cupolas on a patented conveyor not yet put in place. Chalcopyrite ore, high in silica, from the Massey mine is to be used in the cupolas with calcined matte. The plant is located on the side of a steep hill, the crusher at *B* being 25 ft. above the floor of the calciners. The crushers, calciners and furnaces occupy a space 180×160 ft. under one roof and the plant is planned to handle materials as cheaply as possible by utilizing gravity.

*Shuler's Process of Treating Sudbury Ores.*—Dr. Shuler has proposed the

the use of magnetic separators to remove the iron and nickel minerals from the Sudbury ores which, he believes, will yield a nickel ore containing as little as from 1 to 0.2% Cu, an amount too small to interfere with the finished steel made from these ores. The nickel portion, which carries most of the iron and sulphur, is dead roasted, briquetted and smelted into nickeliferous pig iron in an iron blast furnace. As the Sudbury ores carry but little phosphorus and as most of this is removed by the magnetic separation, the resultant pig iron will be very low in phosphorus, 0.03% P or less. (United States Patent No. 697,370 of April 8, 1902.)

**Browne's Electrolytic Process for Depositing Nickel.**—It is understood that for some months a plant near Cleveland, O., has been producing from 8 to 15 tons of nickel per month, operating under a Canadian patent of David H. Browne.<sup>1</sup> This electrolytic process consists of the following steps: Anodes of copper-nickel alloy and cathodes of pure copper are suspended in a solution of copper-nickel chlorides which is continuously regenerated by passing it through

1. Anodes. B. Cathodes. C. Electrolytic. D. Water-sealed anode cell. E. Pipe from ammonia tanks. F. Pipe conveying chlorine gas to tower.

### 3. 2.—BROWNE'S ELECTROLYTIC PROCESS FOR THE ELECTROLYTIC SEPARATION OF NICKEL AND COPPER.

tower filled with Bessemerized matte or alloy to be treated, in contact with salt solution and chlorine gas evolved from the nickel precipitating process. When the electrolyte is rich in nickel, and the copper nearly all deposited on the copper cathode, the remaining copper and the iron are precipitated therefrom in turn by hydrogen sulphide or a similar reagent, and I am informed, ammonia, and the nickel chloride solution electrolyzed in contact with carbon anodes in a water-sealed compartment (see Fig. 2) and pure sheet nickel cathodes. The chlorine evolved from the anode compartment is conveyed to the regenerating tower.

**Ulke's Continuous Electrolytic Process for Separating Nickel and Copper.**—With the Ulke process it is most advantageous to use a material consisting of not less than 20% Ni and not less than 80% Cu, which is cast into anode plates. The electrolyte consists of a solution of copper and nickel sulphate, and contains an excess of free sulphuric acid,—and the cathodes are of pure sheet copper. The electrolyte is heated and kept in circulation, and from time to time portions of it

<sup>1</sup> No. 74,401 of Jan. 14, 1902, reissue of No. 69,729 of Dec. 21, 1900.

at carrier, a primary deposition of nickel occurs, which increases with the further dilution of the electrolyte near the cathode. Since a primary deposition of nickel is powdered and black, dilute solutions and high current densities are to be avoided. 5. By circulating, stirring or heating the electrolyte, the differences in concentration are equalized, and a higher cathode current density may be employed. Whenever the electrolyte contains a metallic salt capable of different degrees of oxidation, a counter electromotive force is produced which varies with the different metals as anodes, according to the difference in the rise of potential, between the anodes and the normal electrolyte.

*Electrolytic Separation of Cobalt from Nickel.*—D. Balachowsky<sup>4</sup> suggests the separation of cobalt from an acetic acid solution of the metals, to which has been added for each 0.3 g. of metal, 3 g. of ammonium thiocyanate, 1 g. of urea, and from 1 to 2 c.c. of ammonia to neutralize the excess of acetic acid, the whole diluted to 100 c.c. A maximum E.M.F. of 1 volt, and a minimum current density of 0.8 amperes is employed, at a temperature of from 70 to 80°C. The cobalt is retained in solution while the deposited nickel is dissolved from the cathode by nitric acid and the solution filtered to remove the sulphur from the sulphide plated on the cathode, and electrolytically treated in the presence of ammonia. The cobalt solution is evaporated, acidified with nitric acid, filtered, and electrolyzed. Cobalt is extensively used in Europe for the production of a bright purple dye. In America, at the American Nickel Works, in N. J., cobalt oxide is prepared from cobalt ores from Mine la Motte, Mo. *Nickel Alloys.*—Nickel aluminum sheet is now made commercially with a tensile strength of 40,000 lb. per sq. in., and an elastic limit of 25,000 lb. per sq. in. Its price is the same as for aluminum sheets of the same size and thickness. Other alloys of aluminum and nickel are described elsewhere in this volume in the section devoted to aluminum.

*Ferro-nickel*, containing 25, 35, 50, and 75% nickel respectively, and analyzing 1% C, 0.3% Si, 0.02% S, and 0.03% P, is manufactured in large quantities so that the percentage of nickel required in steel may be absolutely controlled. The ferro-nickel is malleable and homogeneous and may be readily rolled into sheets.

*Chrome-nickel* containing usually 73% Cr, 23% Ni, 2.5% Fe, 1% C, and 0.5% Si, is used in making a high-grade steel containing fixed percentages of chromium and nickel, to be utilized in the manufacture of armor plate and projectiles. Plates made by this process are said, when tempered, to be superior to ordinary steel armor-plates.

*Tungsten-nickel* is now supplied by several firms, for steel manufacture, with a general composition of 23% Ni, 73% W, 2.5% Fe, 1% C, and 0.5% S.

*Molybdenum-nickel* alloy may be obtained in a fused state, instead of the form commonly produced. Its composition ranges from 45 to 75% Mo, 50% Ni, 2 to 2.5% Fe, 1 to 1.5% C, and 0.25 to 0.5% S. The use of molybdenum in powdered form led to an irregular product caused by the losses of molybdenum by oxidation, and the substitution of a fused alloy, is said to give an absolutely uniform product, containing a percentage of molybdenum

<sup>4</sup> *Comptes Rendus*, 162 (24), 1493-1495.

## OCHER AND IRON OXIDE PIGMENTS.

THE production of all mineral paints, including ocher, umber, sienna and iron oxide in 1901 was 43,036 short tons, valued at \$516,306, as compared with 41,917 short tons, valued nominally at \$461,087 in 1900, while the imports of these products were respectively 11,149,274 and 10,974,544 lb. The production of Venetian and Indian reds in 1901 was 9,201 short tons, valued at \$153,467, as compared with 6,352 short tons, valued at \$110,658 in 1900. The leading States in the production of ocher are Pennsylvania, Georgia, California and Vermont, while iron oxide comes largely from New York, Pennsylvania and Tennessee. UMBER and sienna are produced chiefly in Illinois and Pennsylvania. Under Venetian and Indian red is included only the pigment made by calcination of copperas. The chief producers are the American Steel & Wire Co., at Waukegan, Ill., and Worcester, Mass.; C. K. Williams & Co., Allentown, Pa.; S. P. Wetherill & Co., Philadelphia, Pa.; and Mephram & Klein, St. Louis, Mo.
